VPH	Vehicles Per Hour

1.0 Introduction

1.1 Project Description

The Florida Department of Transportation (FDOT) District One is preparing a Master Plan for Interstate 75 (I-75) in Sarasota County and Manatee County. The study limits in Sarasota County start from east of SR 777 (N River Road) to the Sarasota/Manatee County Line (22.8 miles). The study limits in Manatee County start from the Sarasota/Manatee County Line to north of Moccasin Wallow Road (16.5 miles). The Master Plan covers a total of 39.3 miles and traverses the major urban areas of Sarasota and Bradenton in southwest Florida. I-75 also crosses the navigable Manatee River in Manatee County near the northern project limit.

The project segment of I-75 consists of a six-lane divided typical section with a maximum posted speed limit of 70 miles per hour (mph). The functional classification of I-75 within the Master Plan limits is Urban Principal Arterial – Interstate. Existing right of way (ROW) along the corridor ranges from approximately 300 feet to 500 feet in width. While the proposed improvements are anticipated to be constructed primarily within the existing ROW, some additional ROW may be required, particularly around the interchanges. Specific ROW requirements will be determined during Project Development and Environment (PD&E) studies for various segments of this Master Plan as funding becomes available.

This capacity improvement project involves the potential construction of managed lanes in each direction on I-75. Additional general use lanes, collector-distributor roadways, and auxiliary lanes, as well as interchange operational improvements, are also being considered. As such, up to a fourteen-lane typical section is being explored. There are also opportunities to operate reliable, efficient transit service within the managed lanes, as well as to provide connections to park and ride or kiss and ride lots located within the project area. **Figure 1-1** shows the project location map for the I-75 North Corridor Master Plan.

1.2 Project Background

The I-75 from N River Road to Moccasin Wallow Road Master Plan is part of FDOT District One's Southwest Connect Projects to improve and/or provide managed lanes on the interstate system throughout much of District One. The other two project segments include Interstate 4 (I-4) from West of SR 570 (Polk Parkway) to West of US 27 and the I-75 South Corridor from east of Collier Boulevard (SR 951) to Bayshore Road (SR 78).

These three studies will analyze the existing traffic volumes and future demand on the interstate system and provide a regional perspective to identify the areas where future improvements are needed. The improvements identified in these studies may include interstate widening, managed lanes, collector-distributor roadways, auxiliary lanes, modifying interchanges, and evaluating the possibility and need for new interchanges.

Figure 1-1 Project Location Map

1.3 Purpose and Need

The purpose of the Master Plan is to address the deficient operational capacity of I-75, also known as Florida's State Road (SR) 93, from east of N River Road in Sarasota County to Moccasin Wallow Road in Manatee County to accommodate future travel demand projected as a result of population and employment growth along the corridor. The project will evaluate the potential addition of managed lanes, including supporting additional general use lanes, collector-distributor roadways, and auxiliary lanes; interchange operational improvements will also be considered. Other goals of the project are to:

1. Preserve the operational integrity and regional functionality of I-75 (and, therefore, the regional transportation network) by complementing similar corridor improvements to the north and south, and
2. Enhance emergency evacuation and response times.

The need for this project is based on the following criteria:

Capacity: The project is anticipated to improve traffic operations along I-75 by increasing capacity and better dispersing traffic (i.e., separating managed lanes traffic from general use traffic). The traffic dispersal and reduced congestion can decrease vehicle conflicts and, therefore, enhance travel conditions along the corridor. I-75 within the project limits currently operates at Level of Service (LOS) B to E, with annual average daily traffic volumes ranging from 75,000 vehicles per day to 139,000 vehicles per day. Traffic volumes on the corridor are projected to increase to between 113,000 and 211,000 vehicles per day by 2045. Without improvements, the driving conditions are expected to deteriorate below acceptable LOS targets.

Safety: I-75 serves as part of the emergency evacuation route network designated by the Florida Division of Emergency Management. Also designated as an evacuation facility for Sarasota and Manatee Counties, I-75 is vital in facilitating traffic during emergency evacuation periods as it connects to other major arterials and highways of the state evacuation route network, such as N River Road and US 301. The project is anticipated to:

- Improve emergency evacuation capabilities by enhancing connectivity and accessibility to other major arterials designated as part of the state evacuation route network, and
- Increase the volume of traffic that can be evacuated during an emergency event.

System Linkage: As part of Florida's Strategic Intermodal System (SIS) highway network, I-75 plays a significant role in facilitating commuter, visitor, and freight traffic within the state. The proposed project improvements are part of a larger, regional set of projects on the interstate system to both the north and south (in Hillsborough, Pinellas, Polk, Charlotte, Lee, and Collier Counties) that are considering managed lanes and additional general purpose lanes, auxiliary lanes, etc. to increase the operational capacity of not only I-75, but I-4 and I-275 as well.

The intent is for all of these project improvements to work together to improve the overall reliability and performance of the interstate system in moving high volumes of goods and people at efficient speeds. It is important to note that managed lanes also create an opportunity for the provision of efficient and reliable transit service. As such, these improvements are critical to enhancing regional mobility. They are also key in preserving the operational integrity and regional functionality of the I-75 corridor as a whole.

1.4 Study Methodology

This Existing Conditions Traffic Technical Memorandum has been prepared in accordance with the approved Traffic Methodology Statement for this project submitted to FDOT in April 2020 (included in **Appendix A**), the Safety Methodology Statement for this project submitted to the FDOT in August 2019 (shown in **Appendix B**), and the Traffic Analysis Memorandum of Agreement (MOA) finalized with FDOT in June 2020 (shown in **Appendix C**). The study area of influence and study intersections are shown in **Figure 1-2**. A list of these intersections is provided in **Table 1-1** and the ID numbers are included in the traffic figures provided in Section 6.3.

The analysis years used in this project are as follows:

- Existing Year – 2019
- Opening Year – 2025
- Design Year – 2045

2.0 Roadway Characteristics

I-75 is a SIS highway corridor on the State Highway System (SHS) operating as a divided, limited-access facility with six 12-foot lanes within the study limits. I-275 is also designated as an SIS highway corridor and University Parkway west of I-75 and SR 70 east of I-75 are designated as emerging SIS highway corridors.

I-75 is a major commuter and freight corridor and provides north-south connectivity along southwestern Florida, servicing the North Port, Venice, and Port Charlotte areas to the south and the Siesta Key, Sarasota, Lakewood Ranch, and Bradenton areas to the north within the study limits. I-75 provides access to and from 13 interchanges within the study limits, including the systems interchanges of I-275 and SR 681. **Table 2-1** shows the roadway characteristics of I-75, I-275, and interchange cross streets within the study area.

I-75 NORTH CORRIDOR MASTER PLAN

EXISTING CONDITIONS TRAFFIC TECHNICAL MEMORANDUM

3.0 Traffic Data Collection

3.1 Transportation System Data

Available existing traffic data for the I-75 mainline and ramps was obtained from FDOT District One. All other traffic data was determined using the procedures described below. Additional sources of information also included: Straight Line Diagrams (SLDs), Roadway Characteristic Inventory (RCI) Data, Florida Geographic Data Library (FGDL) Geographic Information System (GIS) Data, and the FDOT Florida Traffic Online Database (2018).

3.2 Existing and Historical Traffic Data

Data collection for the Master Plan consists of information from various sources, including traffic count information, the latest five years of crash history (2013 to 2017), StreetLight Insight origin-destination (OD) data, and the District One Regional Planning Model version 1.0.6 (D1RPM) 2015 Validated Base Model and 2040 Cost Feasible Model.

3.2.1 Traffic Counts

In accordance with the Manual on Uniform Traffic Studies (MUTS) and the Project Traffic Forecasting Handbook, traffic count data was collected in the field within the study area, as shown in **Appendix D**. Traffic data collection occurred primarily from August 2019 through December 2019. There were 29 72-hour bi-directional classification counts, 102 72-hour bi-directional volume counts, and 75 turning movement counts (TMCs) collected between 7:00 AM to 9:00 AM and 4:00 PM to 6:00 PM on typical weekdays (Tuesday, Wednesday, or Thursday). The TMCs include pedestrian, bicyclist, and truck volumes, as well as a peak-hour volume summary per intersection.

3.2.2 Field Data

Field data was collected for microsimulation calibration purposes, including I-75 mainline peak and off-peak speeds from the Regional Integrated Transportation Information System (RITIS) and arterial travel times using Bluetooth stations. Field visits were also conducted to collect information on existing driver behavior, queuing, and congestion levels and to observe signal behavior, such as protected/permitted left-turn operations, right-turn-on-red (RTOR) restrictions, phasing, etc.

Existing signal plans and timing information for signalized intersections were obtained from Sarasota County and Manatee County for use in the microsimulation modeling efforts and can be found in **Appendix E**. Origin-Destination (OD) data was collected from StreetLight Insight data. StreetLight Insight uses data derived from navigation-Global Positioning System (GPS) data and other location-based data from connected cars, trucks, traffic apps, traffic counts, points of interest, and third-party aggregators to identify travel patterns and provide OD and travel time information.

3.2.3 Crash Data

Crash data was obtained for the study area from FDOT's Crash Analysis Reporting (CAR) Online and the University of Florida's Signal Four (S4) crash database for the five-year analysis period from 2013 to 2017 and can be found in **Appendix F**. The data collected includes the number of crashes, the type and location of each crash, the road surface, weather, and lighting conditions of each crash, the number of fatalities and injuries, and the estimate of property damage and economic loss. Crash data was collected for the I-75 mainline from east of N River Road in Sarasota County to north of Moccasin Wallow Road in Manatee County, as well as for each of the study corridors and study intersections.

4.0 Historical Crash Analysis

The following sections summarize the analysis of the historical crash data for the I-75 North Corridor Master Plan. Unless otherwise stated, the crash data analyzed is from 2013-2017. There was a total of 5,314 crashes involving 36 fatalities and 3,109 injuries. Analysis of the study area was broken out into 66 interstate segments, 60 ramp segments, 57 arterial segments, and 66 arterial intersections. Of the 66 interstate segments, 19 (29 percent) have a crash rate that is significantly higher than the statewide average for similar roadway facilities. Additionally, two (3.5 percent) of the 57 arterial segments and 12 (18 percent) of the 66 arterial intersections contain a crash rate that is significantly higher than the statewide average. This section will focus on those high crash rate locations. Safety memorandums showing the historical crash analysis for each study interchange and the associated study intersections, including those not included here that do not have high crash locations, can be found in **Appendix G**.

4.1 Crash Rates

A summary of the statewide average crash rates by facility type from the CARS database is provided in **Table 4-1**. In order to identify locations of concern within the I-75 North Corridor Master Plan, high crash rate locations have been identified in **Table 4-2** for all interchanges in the study area. The determination of high crash rate locations was performed using the procedure detailed in the FDOT CARS User Manual to determine the level of confidence (i.e., the high crash confidence) that a location's crash rate is higher than the statewide average for 2013 to 2017 based on the location's facility type. Locations with a high crash confidence of 95 percent or higher were determined to have a crash rate that is statistically significantly higher than the statewide average. These locations have an actual crash rate that is significantly higher than the statewide average, with a high crash confidence of 95 percent or higher. The interchanges that include high crash locations are discussed below in further detail. The ramp segments connecting the interstate to the arterial at each interchange do not have a statewide average crash rate associated with their facility type.

I-275/US 41 Interchange Area:

The northbound I-75 ramp terminal intersection has a crash rate that is significantly higher than the statewide average.

I-75/US 301 Interchange Area:

Two locations have a crash rate that is significantly higher than the statewide average including US 301 between the northbound and southbound ramp terminals and the US 301/60th Avenue intersection.

I-75/SR 64 Interchange Area:

Three locations have a crash rate that is significantly higher than the statewide average including the SR 64/64th Street Court E/66th Street Court E intersection, the northbound I-75 segment at the off-ramp to westbound SR 64, and the southbound I-75 segment at the on-ramp from westbound SR 64.

I-75/SR 70 Interchange Area:

Five locations have a crash rate that is significantly higher than the statewide average including SR 70 east of the northbound I-75 ramp terminal, the southbound I-75/SR 70 ramp terminal intersection, the Creekwood Boulevard/52nd Place East intersection, southbound I-75 at the on ramp from westbound SR 70, and northbound I-75 at the off ramp to westbound SR 70.

I-75/University Parkway Interchange Area:

Five locations have a crash rate that is significantly higher than the statewide average including the University Parkway/Cattlemen Road/Cooper Creek Boulevard intersection, as well as both directions of the I-75 mainline segments north and south of the interchange.

I-75/SR 780 (Fruitville Road) Interchange Area:

Five locations have a crash rate that is significantly higher than the statewide average including the southbound I-75 ramp terminal, the Fruitville Road/Cattlemen Road intersection, the northbound I-75 on ramp from eastbound Fruitville Road, the northbound I-75 off ramp to Fruitville Road, and the southbound I-75 on ramp from westbound Fruitville Road.

I-75/SR 758 (Bee Ridge Road) Interchange Area:

Two locations have a crash rate that is significantly higher than the statewide average including the southbound I-75 ramp terminal intersection and the northbound I-75 segment at the on ramp from eastbound Bee Ridge Road.

I-75/SR 72 (Clark Road) Interchange Area:

Four locations have a crash rate that is significantly higher than the statewide average including the intersections at both I-75/SR 72 (Clark Road) ramp terminals and the I-75 mainline at the on ramps from Clark Road in both the northbound and southbound directions.

I-75/Jacaranda Boulevard Interchange Area:

Only the northbound I-75 segment at the off-ramp to Jacaranda Boulevard has a crash rate that is significantly higher than the statewide average.

I-75/N River Road Interchange Area:

Five locations have a crash rate that are significantly higher than the statewide average including the N River Road at East Venice Avenue intersection as well as both directions of the I-75 mainline segments north and south of the interchange.

Table 4-1 Five-Year Statewide Average Crash Rates (2017) by Facility Type

Area Type	Average Crash Rate Category	Statewide Average Crash Rate
Suburban	6+ Lanes 2 way Divided	2.711
	6+ Lanes 2 way Divided 3 Legs	0.343
	6+ Lanes 2 way Divided 4 Legs	0.749

4.2 Crash Types

In general, rear-end crashes were the most common crash type at the previously identified high crash locations. Only Creekwood Boulevard near the I-75/SR 70 interchange and US 41 showed different common crash types, with the most common crash types being angle and left-turn crashes, respectively. **Table 4-3** details the total number of crashes at high crash locations separated by crash type.

Table 4-3 High Crash Location Common Crash Types

Location		On Street Common Crash Type	Common Crash Type %	Common Crash Type Count	Total Crashes
Interchanges	I-75/SR 64	Rear End	46.2%	42	91
	I-75/SR 70	Rear End	67.2%	88	131
	I-75/University Pkwy	Rear End	61.9%	304	491

4.3 Lighting, Weather, and Road Surface Conditions

Twenty percent of crashes at high crash locations took place in wet/slick/unpaved and standing water roadway conditions, accounting for 471 total crashes. Seven percent of crashes at high crash locations took place in dark conditions with no lighting, accounting for 154 total crashes. **Table 4-4** details the total number of crashes within the study area separated by roadway surface and lighting conditions.

Table 4-4 High Crash Location Contributing Factors Summary

Interchange Location	Percent of Total Crashes at High Crash Locations		Total Crashes at High Crash Locations		Total Crashes at Interchange High Crash Locations

Total	7%	20%	154	471	2336

4.4 Injury Severity

Table 4-5 summarizes crashes for all locations (including locations without a high crash rate) in the study area by severity. Of the 5,314 total crashes, there were 34 fatal crashes, 1,921 crashes involving personal injury, and 3,359 crashes that were property damage only. The FDOT KABCO crash costs from the FDOT Design Manual 2020 are summarized in **Table 4-6** for all locations (including locations without a high crash rate).

Table 4-5 Crash Severity Summary

Category	2013	2014	2015	2016	2017	Total	Mean	Percentage
Fatal	3	6	7	12	6	34	6.8	0.60%
Severe Injury	38	47	95	113	94	387	77.4	7.30%
Moderate Injury	87	105	86	93	87	458	91.6	8.60%
Minor Injury	175	203	203	264	231	1,076	215.2	20.20%
Property Damage Only	479	572	832	754	722	3,359	671.8	63.20%
Total	782	933	1,223	1,236	1,140	5,314	1,062.8	100.00%

Table 4-6 FDOT KABCO Crash Costs

Crash Severity	Comprehensive Crash Cost
Fatal (K)	\$10,670,000
Severe Injury (A)	\$872,612
Moderate Injury (B)	\$174,018
Minor Injury ©	\$106,215
Property Damage Only (O)	\$7,700

Table 4-7 summarizes crash severity and comprehensive crash costs by location for high crash locations. Overall, there were 9 fatal crashes, 163 severe injury crashes, 174 moderate injury crashes, 466 minor injury crashes, and 1,524 property damage only crashes for a total of 2,336 crashes occurring at high crash locations. These crashes had an estimated comprehensive crash cost of \$329,775,878, which is an average of \$65,955,176 per year.

The average cost per crash at each location was calculated by dividing the total crash cost by the total crashes. This was then compared to the statewide average cost per crash based on the FDOT KABCO Crash Costs by Facility type Table 122.6.1 from the FDOT Design Manual 2020. These tables and the summary of the statewide average cost per crash are included in **Appendix G**. Overall, 10 locations had costs per crash higher than the statewide average. The location with the highest comprehensive crash cost was the northbound I-75 segment at the on-ramp from N River Road, with an estimated total five-year crash cost of \$11,636,805. This location also had the highest average cost per crash at \$785,563.

Table 4-7 Crash Severity for High Crash Locations

4.5 Contributing Causes for High Crash Locations

A summary of crashes by driver contributing cause for the high crash locations is shown in **Table 4-8**. Among the contributing causes documented in the crash data, careless/negligent driving (1,426 crashes, 61.0 percent) was the highest.

Table 4-8 Contributing Causes for High Crash Locations

Category	2013	2014	2015	2016	2017	Total	Mean	Percentage

5.0 Multimodal Accommodations

5.1 Pedestrian and Bicyclists

The existing pedestrian facilities along corridors within the study area are as follows:

- N River Road: sidewalks are not present along this corridor and crosswalks are not present at ramp terminal intersections;
- Jacaranda Boulevard: sidewalks are not present along this corridor. Crosswalks are provided on the east, west, and north legs of the south ramp terminal intersection;
- Laurel Road: sidewalks are not present along this corridor and crosswalks are not present at ramp terminal intersections;
- SR 681: sidewalks are not present along this corridor and crosswalks are not present at ramp terminal intersections;
- SR 72 (Clark Road): sidewalks are not present along this corridor and crosswalks are not present at ramp terminal intersections;
- SR 758 (Bee Ridge Road): sidewalks are present along the south side of this corridor and crosswalks are present on the south sides of the ramp terminal intersections, allowing the interchange to be traversed in the east-west direction. There are no crosswalks leading to the north side of Bee Ridge Road. The Bee Ridge Road/Cattlemen Road intersection, just west of the I-75/Bee Ridge Road interchange, has crosswalks on all four legs and sidewalks on both sides of the road on the north and west legs and on the west side of the road on the south leg;
- SR 780 (Fruitville Road): sidewalks are not present along this corridor through the interchange area and crosswalks are not present at ramp terminal intersections. The Fruitville Road/Cattlemen Road intersection west of the I-75/Fruitville Road interchange has crosswalks on all legs and has sidewalks on both sides of the west and north legs. The Fruitville Road/Lakewood Ranch Boulevard intersection east of the I-75/Fruitville Road interchange has crosswalks on all legs and has sidewalks on both sides of the east, north, and south legs;
- University Parkway: sidewalks are present along the north and south sides of this corridor through the interchange area with the exception of pedestrians crossing into the core of the Diverging Diamond Interchange (DDI). Crosswalks are present at the ramp terminal intersections. The University Parkway/Cattlemen Road intersection west of the I-75/University Parkway interchange has crosswalks on all legs and has sidewalks on both sides of all legs, except the north side of the west leg. The University Parkway/Market Street intersection east of the I-75/University Parkway interchange has crosswalks on all legs, except the east leg, and has sidewalks on both sides of all legs;
- SR 70: sidewalks are present along both the north and south sides of this corridor and crosswalks are present in the eastbound and westbound directions at both ramp terminals. A north-south crosswalk is provided at west terminal, but not the east terminal;
- SR 64: sidewalks are present along both the north and south sides of this corridor and crosswalks are present in the eastbound and westbound directions at both ramp terminals. North-south crosswalks are not provided at either ramp terminal intersection;
- US 301 (Ellenton): sidewalks are not present along this corridor through the interchange area and crosswalks are not present at ramp terminal intersections;
- I-275 at US 41: sidewalks are not present along US 41 and crosswalks are not present at ramp terminal intersections, and

- Moccasin Wallow: sidewalks are not present along this corridor and crosswalks are not present at ramp terminal intersections.

The existing bicyclist facilities along corridors within the study area are as follows:

- N River Road: bicycle lanes are not present;
- Jacaranda Boulevard: bicycle lanes are not present;
- Laurel Road: bicycle lanes are not present;
- SR 681: bicycle lanes are not present;
- SR 72 (Clark Road): bicycle lanes are not present;
- SR 758 (Bee Ridge Road): bicycle lanes are not present. However, bicycle keyholes develop from the shoulders on the west leg (eastbound) of the Bee Ridge Road/Mauna Loa Boulevard intersection, just east of the I-75/Bee Ridge Road interchange. There are no bicycle keyholes within the I-75/Bee Ridge Road interchange;
- SR 780 (Fruitville Road): bicycle lanes are present in both the eastbound and westbound directions through this interchange. The eastbound bicycle lane is carried along the outside without the use of keyholes and crosses the southbound on ramp and eastbound-to-northbound loop on ramp perpendicularly. The westbound bicycle lane is carried along the outside with the use of keyholes at the northbound on ramp and westbound-to-southbound loop on ramp;
- University Parkway: bicycle lanes are present in both the eastbound and westbound directions through this interchange and at the Cattlemen Road and Market Street intersections;
- SR 70: bicycle lanes are present in both the eastbound and westbound directions through this interchange with bicycle keyholes used where applicable;
- SR 64: bicycle lanes are present in both the eastbound and westbound directions through this interchange with bicycle keyholes used where applicable;
- US 301 (Ellenton): bicycle lanes are present in both the eastbound and westbound directions through this interchange with bicycle keyholes used where applicable. Green paint is used on the bicycle lane in the westbound direction through the weaving area of the two loop ramps;
- I-275 at US 41: bicycle lanes are present in both the northbound and southbound directions through this interchange. There is a striped buffer between the bicycle lanes and vehicle travel lanes within the core of the interchange. The southbound bicycle lane runs between the southbound lanes and the eastbound-to-southbound off ramp lane at the south terminal. The eastbound-to-southbound off ramp lane yields to the bicycle lane before merging into the southbound US 41 travel lanes. This is a different treatment than what is deployed at the corresponding north terminal. At the north terminal, the bicycle lane crosses over the westbound-to-northbound off ramp and continues north along the outside. Bicycle keyholes are used where applicable between the intersections of US 41 with 73rd Street E-69th Street E and Orange Grove Boulevard-85th Street E, and
- Moccasin Wallow: bicycle lanes are present in both the eastbound and westbound directions through this interchange and bicycle keyholes are used to lead the bicycles between the travel lanes and on- and off-ramp right turns.

5.2 Transit

Sarasota County Area Transit (SCAT) provides bus services along corridors within the study area as follows:

- N River Road: Route 100 (Airport/Downtown/North Port) travels along I-75 through this interchange;
- Jacaranda Boulevard: Route 100 (Airport/Downtown/North Port) travels along I-75 through this interchange;
- Laurel Road: Route 100 (Airport/Downtown/North Port) travels along I-75 through this interchange;
- SR 681: Route 100 (Airport/Downtown/North Port) travels along I-75 through this interchange;
- SR 72 (Clark Road): Route 100 (Airport/Downtown/North Port) travels along I-75 through this interchange. Route 15 (Pavilion/Cattlemen/UTC Mall) travels through Gantt Road in the vicinity of the I-75 interchange area;
- SR 758 (Bee Ridge Road): Route 100 (Airport/Downtown/North Port) travels along I-75 south of this interchange and continues along Bee Ridge Road west of I-75 to connect both ends of this route. Route 14 (Downtown/Siesta Key Mall/Bee Ridge) traverses the I-75 interchange area to connect both ends of this route. Route 15 (Pavilion/Cattlemen/UTC Mall) travels through Cattlemen Road in the vicinity of the I-75 interchange area;
- SR 780 (Fruitville Road): Route 1 (Downtown/Fruitville/Cattlemen/Sarasota Center Boulevard) bypasses the I-75 interchange area between Cattlemen Road and Lakewood Ranch Boulevard by using the south leg of Cattlemen Road, Palmer Boulevard, and Apex Road-Coburn Road to connect both ends of this route. Route 15 (Pavilion/Cattlemen/UTC Mall) travels through Honore Avenue in the vicinity of the I-75 interchange area.

Manatee County Area Transit (MCAT) provides bus services along corridors within the study area as follows:

- University Parkway: No transit service;
- SR 70: Route 12 (SR 70) traverses the I-75 interchange area to connect both ends of this route;
- SR 64: Route 3 (Manatee Avenue) travels along SR 64 and turns around via 66th Street Court E and 67th Street Circle E, just west of the I-75 interchange, to connect both ends of this route. The Beach Express (BE) Trolley runs on Sundays and holidays along SR 64 and turns around at the Walmart Supercenter west of the I-75 interchange to connect both ends of this route;
- US 301 (Ellenton): Route 1 (Ellenton Outlet Mall) traverses the I-75 interchange area to connect both ends of this route;
- I-275 at US 41: No transit service;
- Moccasin Wallow: No transit service.

The SCAT and MCAT existing transit line maps are shown in **Appendix H**.

6.0 Existing Year (2019) Volume Development

The following sections summarize the development of the existing year (2019) traffic volumes for the I-75 North Corridor Master Plan. Further detail for each study interchange and intersection can be found in **Appendix I**.

6.1 Design Traffic Parameters

Design traffic factors were determined for the I-75 North Corridor Master Plan based on the collected traffic data, historically observed factors, and forecasted factors from the D1RPM version 1.0.6, with base year 2015 and horizon year 2040. The factors were developed based on the procedures outlined in the *FDOT Project Traffic Forecasting Handbook, 2019*. **Table 6-1** and **Table 6-2** summarizes the existing traffic characteristics and recommended design traffic factors, respectively. These values were used in the development of the existing year (2019) design hour volumes.

6.2 Methodology

The following summarizes the steps that were taken to convert the existing year (2019) AADT for the I-75 North Corridor Master Plan to existing year (2019) turning movement volumes. Further detail can be found in the Traffic Methodology Statement in **Appendix A**.

1. Seasonal and axle correction factors were obtained from *FDOT Florida Traffic Online (2019)* and applied to the 48-hour and 72-hour counts to obtain existing year (2019) AADT for the surface streets. AADTs from *FDOT Florida Traffic Online (2019)* were directly used for the I-75 mainline. **Figure 6-1** through **Figure 6-14** show the existing year (2019) AADT volumes for the I-75 North Corridor Master Plan.
2. K-factors and D-factors were then applied to the AADTs to determine directional design hour volumes (DDHVs) for each of the external nodes of the study area. Based on a review of the field data, a standard K-factor of 0.09 was used on I-75 and arterial roadways. Field collected peak-to-daily ratios were used for driveways and minor non-arterial roads. **Table 6-1** provides interchange level average peak-to-daily ratios as a point of reference, however the peak-to-daily ratios for individual count locations may vary. The D-factors, as presented in **Table 6-2**, are generally constrained to the maximum values provided in the 2019 *FDOT Project Traffic Forecasting Handbook*, however field collected counts exceeding these maximum values are used for driveways and minor non-arterial roads.
3. The external DDHVs were used, along with a base OD matrix from the Base Year 2015 D1RPM, as inputs to the TFlow Fuzzy demand matrix adjustment methodology within PTV's Visum software (version 17), along with seasonally adjusted, field collected turning movement counts, to determine the existing year (2019) turning movement volumes. The existing turning movement counts from the data collection effort were used as targets within the Visum network. This method was used to balance the unbalanced field collected volumes.
4. The resulting output from Visum was a balanced, system-wide, OD matrix that replicates the existing year (2019) turning movement volumes discussed in the following section. The OD matrix was then manipulated for input into the Vissim microsimulation models.

6.3 Existing Year (2019) Turning Movement Volumes

Based on the above methodology, the AM and PM peak hours were determined to occur from 7:30 AM to 8:30 AM and from 4:45 PM to 5:45 PM, respectively. **Figure 6-15** through **Figure 6-28** show the existing year (2019) peak hour turning movement volumes for the I-75 North Corridor Master Plan. For the microsimulation of the I-75 North Corridor Master Plan study area, three hours of traffic simulation were modeled for each AM and PM peak period, as well as a one-hour network loading interval. The three-hour simulation periods were broken up into 15-minute intervals, consisting of one hour for startup, one hour for the peak, and one hour for dissipation of the peak. The network loading, startup, and dissipation volumes were determined as a proportion of the peak hour volumes based on the collected 72-hour approach counts.

Table 6-1 Existing Traffic Characteristics

Interchange	AM Peak Hour	PM Peak Hour

7.0 Simulation Model Development

7.1 Methodology

The existing conditions simulation models for the study area were developed using Vissim version 2020 (service pack 10), a widely used, behavior-based multi-purpose traffic microsimulation program. Vissim tracks individual vehicle movements and interactions with more detail than typical Highway Capacity Manual (HCM) methods and quantifies the performance of individual movements and overall delays and queue lengths for freeways, ramps, and intersections. The 2019 update of the Federal Highway Administration's (FHWA's) Traffic Analysis Toolbox Volume III: Guidelines for Applying Traffic Microsimulation Modeling Software and 2014 FDOT Traffic Analysis Handbook were used as a guideline for the development and calibration of the project Vissim models.

Given the size of the study area and the number of interchanges included for analysis, subarea Vissim models were developed and calibrated for each interchange area and the I-75 mainline and ramps using the calibration measures discussed in Section 8.0. The calibrated subarea models were merged into a single model by combining the individual interchange models with the I-75 mainline model. The combined model was verified for calibration and then used for the analysis of existing conditions. Model assumptions, parameters, and network coding techniques are discussed in the following subsections. All assumptions are based on the traffic data collected in the field between August 2019 and December 2019. Additional site visits were conducted in November 2019 to verify network elements and to observe general driver behavior and localized calibration parameters.

7.2 Data Inputs

Multiple data sources were used to develop the data inputs and calibration targets used in the existing conditions Vissim models. Raw traffic counts were adhered to as closely as possible for calibration. This adherence to the true measured counts provides a more reasonable expectation that other field measurements can be replicated in the model. Detailed information on the development of traffic volumes for calibration and analysis is provided in Section 6.0. Traffic counts, signal timing plans, and spot speeds from RITIS were used for model inputs. Measured travel times (arterial), traffic counts, and spot speeds on I-75 were used to compare with calibration targets. In general, pedestrian, bicycle, and transit components were not modeled unless required for calibration.

7.3 Model Geometrics

Scaled aerial photography obtained from the Land Boundary Information System (LABINS) and Aerial Photo Look Up System (APLUS) was utilized to develop the base Vissim network and establish intersection lane configurations, stop bar locations, and turn bay lengths. The high-resolution aerials were also used to accurately code merge, weave, and diverge sections on the I-75 mainline, according to the lane striping. The geometry was verified using online mapping services, particularly in cases where there appeared to be recent construction.

Portions of the I-75 mainline are currently under construction between University Parkway and SR 64 and construction was ongoing during data collection. Since construction is temporary and involves multiple stages of shifting traffic to different alignments, the existing conditions Vissim models used the pre-construction configuration on I-75. In addition to the mainline construction, the SR 70 interchange is also currently under construction and improvements to the SR 64 interchange were

recently completed. For analysis purposes, the final configurations of the SR 70 and SR 64 interchanges were modeled in Vissim. The SR 64 interchange was nearly complete during data collection and the SR 70 interchange met all arterial calibration targets (travel time and volume) despite data collection occurring during construction (see Section 9.5).

7.4 Vehicle Inputs

Balanced traffic volumes were summarized in 15-minute intervals using existing count data to represent the traffic fluctuations during simulated peak periods which allowed the Vissim models to more closely represent traffic arrival patterns and queuing on the mainline and arterial intersections. A global peak hour of 7:30 AM to 8:30 AM and 4:45 PM to 5:45 PM was determined for the study area. The Vissim models included a 1-hour shoulder period before the peak hour and a 1-hour shoulder period after the peak hour. Due to the length of the I-75 corridor (39.3 miles) and the time it takes to traverse the entire network, a 1-hour seeding period was used prior to the start of the first shoulder hour. The seeding period allows for vehicles to be loaded into the network before recording simulation results.

7.5 Traffic Composition

Traffic compositions (car and truck percentages) for calibration were derived from existing count data for all arterial model inputs. Truck percentages on the primary interchange arterial inputs ranged from 1 to 12 percent, with higher truck percentages (up to 30 percent) identified on some cross-streets and driveways. Truck percentages on the I-75 mainline inputs were calculated following FDOT guidelines, which assumes that peak period truck percentages are half of the daily truck percentage. The peak period truck percentages for I-75 were 7 percent in the northbound direction and 6 percent in the southbound direction. The peak period truck percentage for southbound I-275 was 4 percent. Traffic compositions varied slightly between the calibration and seasonally adjusted volumes used for analysis, but also ranged from 1 to 12 percent on the primary interchange arterial inputs.

7.6 Vehicle Routing

Traffic patterns in Vissim were modeled using static routes and routing decisions. Vehicle routing through the study area was achieved through the development of OD matrices. The OD matrices were developed in 15-minute intervals over a 24-hour period for both cars and trucks using temporal distributions from existing tube counts. Separate routing decisions were modeled for each vehicle class (car and truck) based on the different OD matrices and included 15-minute static route volumes for the entire 4-hour AM and PM peak periods. Each of the interchange and mainline subarea Vissim models included separate OD matrices that were tied together at the on- and off-ramps when combined into the larger model.

7.7 Speed Distributions

Speed distribution profiles were developed for I-75 based on weekday (Tuesday-Thursday) off-peak spot speed data collected from RITIS. The average spot speed data was used to develop speed profiles per lane along the entire I-75 corridor, particularly between interchanges. The use of per lane speed distributions allowed the Vissim models to more accurately represent field conditions, which included speed differences of 10 mph or more between lane 1 (slow lane) and lane 3 (fast lane) based on the RITIS data. Over 100 speed profiles were developed for northbound and southbound I-75 from south of N River Road to north of Moccasin Wallow Road.

In general, speed limits were used to define the speed distributions on all other roadways within the study area. The speed distributions on the arterials were based on data from previous studies for similar roadway types. Desired speed distributions used in the Vissim models are shown below in **Table 7-1**. With over 100 different speed profiles used on the I-75 mainline, an example distribution for one location has been provided. Desired speed decisions were used in the models to generate desired vehicle speeds at various roadway segments and reduced speed areas were strategically placed in locations where vehicles need to reduce their speed due to roadway alignment or for turning movements at intersections. Separate desired speed decisions and reduced speed areas were applied for both cars and trucks, with truck speeds generally slower than cars. Where applicable, turning movements with two or more lanes also included different speeds per lane for both cars and trucks due to the tighter turning radius on the inside lane versus the outside lane.

Table 7-1 Vissim Speed Distributions

Facility or Speed Function	Posted Speed (mph)	Minimum Speed (mph)	Median Speed (mph)	Maximum Speed (mph)
20 mph	20	18	20	27
25 mph	25	20	27	43
30 mph	30	22	30	46
35 mph	35	24	33	50
40 mph	40	29	39	55
45 mph	45	33	43	57
50 mph	50	37	48	61
55 mph	55	42	53	66
60 mph	60	47	57	67
65 mph	65	45	64	77
70 mph	70	54	68	81
Reg Right Turns	-	9	-	12
Sharp Right Turns	-	6	-	9
Wide Right Turns	-	15	-	19
Reg Left Turns	-	15	-	19
Sharp Left Turns	-	10	-	13
Wide Left Turns	-	17	-	22
U-Turn	-	5	-	8
I-75 Mainline Per Lane Example (Southbound MP 199.3)				
Lane 1	70	48	69	82
Lane 2	70	62	74	82
Lane 3	70	67	78	87

Desired speed decisions from the calibrated existing conditions models will be carried forward to the future year models in areas with existing geometry and new speed decisions will be added where geometric improvements include additional lanes. In general, additional through lanes will utilize the same desired speed decisions as the existing left-most lane and auxiliary lanes will utilize the desired speed decisions from the existing right-most lane. If the existing ramp geometry is modified under future conditions, any desired speed decisions near the ramps will be shifted relative to the gore point. Desired speed decisions for new roadways (CD roads and/or express lanes) will be based on the proposed posted speed.

7.8 Lane Change and Emergency Stop Distance

The look-back or lane change distance defines the distance at which vehicles attempt to change lanes prior to a decision point. The longer the distance, the farther back the driver anticipates their next movement thus impacting lane utilization. For example, drivers on a dual left-turn lane will position themselves based on a downstream turning movement or vehicles will position themselves in the right-hand lane upstream of an interchange entrance ramp. Lane change distances were initially set to a value of 1,500 feet for arterials and adjusted, where necessary, to match field conditions and calibrate congestion levels. Lane change distances for I-75 off-ramps ranged from 2,500 feet to over 2 miles. Known decision making patterns and engineering judgment were also used to modify the look-back distances as needed.

Emergency stop is the last possible position where a vehicle can change lanes. The default value in Vissim for emergency stop distance is 16.4 feet, which was increased to 50 feet for arterials and 150 feet for I-75 off-ramps to allow enough space for vehicles to make decisions prior to being too close to an intersection or diverge location, especially at higher speeds. Similar to the lane change distances, emergency stop distances were adjusted, where necessary, to match field conditions and calibrate congestion levels.

7.9 Signal Operations and Stop/Yield Control

Signal timing and phasing parameters were coded in the AM and PM models using Vissim's ring barrier controller (RBC) module according to the signal timing plans obtained from Sarasota County and Manatee County. All intersections were coded with an individual signal controller except for when an interchange operates both ramp terminals using a single controller. The modeling assumed that RTOR was allowed on all right turns unless they were specifically prohibited with the use of no RTOR signs. Additionally, RTOR was only allowed from the right-hand lane of a dual or triple right-turn movement consistent with field observations unless modified for calibration purposes.

Stop or yield control was coded in the model for unsignalized intersections using a combination of stop signs, conflict areas, or priority rules depending on signage and/or driver behavior. In general, priority rules were used for permitted left-turn movements due to Vissim's inability to properly handle conflicts with both the opposing through lanes and right-turn lane using only conflict areas. Depending on the geometry, Vissim will create two conflict areas and a left-turning vehicle will yield to the opposing through traffic and then yield again if a right-turning vehicle is present at the same time, resulting in the left-turning vehicle yielding in the middle of the through lanes. The use of priority rules provided more control over these conflicting movements and allowed the left-turn movement to properly yield for the opposing right-turn movement. In addition, conflict areas were used at these locations to prevent through vehicles from running over left-turning vehicles. The use of conflict areas allowed the through traffic to "slow down" for vehicles that may sometimes make an aggressive left turn, or for

trucks that are slow to cross the through lanes. The use of priority rules and conflict areas for permitted turns provided a consistent approach across all locations.

7.10 Multiple Model Runs and Simulation Output

Due to the varying nature of the simulations between runs with different random seed numbers, Vissim results can differ from one run to the next. To improve model accuracy, multiple runs are required, and the results should be calculated using an average of these runs. Following the guidelines provided in Section 7.4.4 of the FDOT Traffic Analysis Handbook, the following equation was used to determine the minimum number of runs:

$$n = \left(\frac{s * t_{\frac{\alpha}{2}}}{\mu * \varepsilon} \right)^2$$

Where:

n = required number of simulation runs

s = standard deviation of the system performance measure (such as total traffic volume) based on previously conducted simulation runs.

$t_{\alpha/2}$ = is the critical value of a two-sided student's t -statistic at the confidence level of α and $n-1$ degrees of freedom. An α of 5% is typical.

μ = mean of the system performance measure

ε = the tolerable error, specified as a fraction of μ . A 10% error is desired.

The equation noted above resulted in less than one model run, therefore a minimum of ten runs were performed for the calibration and existing conditions models, with random seed numbers ranging from 1111 to 11110 with increments of 1111.

8.0 Simulation Model Calibration

Calibration is an iterative process that involves adjusting model parameters until the simulation reasonably replicates driver behavior, traffic flow patterns, and field-measured data. The calibration process used for the Vissim models followed FDOT and FHWA guidelines for determining the acceptability of model results as compared to existing operations.

8.1 Visual Checking and Error Correction

The visual checking and error correction process focused on addressing coding errors before the output results were compared to the calibration targets. When making changes to model parameters, error checking reduces the potential that these changes have unintended consequences in the model. This process involved reviewing data inputs, Vissim error reports, and model animations. Data inputs, such as network geometry, traffic volumes, and route choices, were reviewed by the model developer as well as a quality control reviewer. The error report produced after each simulation run may include common errors, such as vehicle removal, signal errors, end-of-link errors, and various others. Critical errors in the model were accounted for and corrected during this step.

Reasonableness checks included visual checking of the animation file to check for abnormal driving behavior or irregular queuing within the network and to identify coding parameters that may have been overlooked. Additionally, modeled throughput was compared to the demand volumes to eliminate large differences between demand and modeled volumes.

8.2 Calibration Targets

The objective of model calibration is to match model performance to the field performance measurements with a pre-determined threshold of acceptable error. This allowable error accounts for limitations in software capabilities and the realization that traffic data and field observations collected on different days will naturally yield different results due to normal fluctuations in traffic patterns. Calibration of the existing AM and PM peak period subarea and combined models used the thresholds indicated in the FDOT Traffic Analysis Handbook Table 7-7 Classical Model Calibration Targets shown in **Table 8-1**.

Traffic volume calibration targets include the Gregory E. Hovers (GEH) statistic, which compares expected or measured volumes with volume output from the microsimulation model and is calculated using the following formula:

$$GEH = \sqrt{\frac{2(m - c)^2}{m + c}}$$

Notes:

m = Model estimated traffic volume from the simulation model (vph)

c = Field measured traffic volume (vph)

Using GEH instead of difference percentages allows for a better acceptance over a wider range of volumes. GEH is not linear and places less importance on links with low expected volumes while allowing for variation at high volume locations. Typically, a GEH of less than 5.0 is considered a good match between the two compared hourly volumes for the same facility. GEH values higher than 5.0 warrant investigation and values over 10.0 indicate there may be an error with the model.

Table 8-1 Vissim Calibration Targets

Calibration Criteria	Calibration Target/Goal
Traffic Volume	Simulated and measured link volumes for more than 85% of links to be: <ul style="list-style-type: none"> • Within 100 vph for volumes less than 700 vph • Within 15% for volumes between 700 vph and 2700 vph • Within 400 vph, for volumes greater than 2700 vph.
	Simulated and measured link volumes for more than 85% of links to have a GEH statistic value of 5 or lower.
	Sum of link volumes within calibration area to be within 5%.
	Sum of link volumes to have a GEH statistic value of 5 or lower.
Speed	Modeled average speeds on I-75 to be within +/- 10 mph of field-measured speeds on at least 85% of all RITIS detector locations.
Travel Time	Modeled arterial travel times within 1 minute (or 15%, if higher) for more than 85% of segments.
Visualization	Check consistency with field conditions of the following: on- and off-ramp queuing; weaving maneuvers; patterns and extent of queue at intersections and congested links; lane utilization/choice; location of bottlenecks; etc.
	Verify no unrealistic U-turns or vehicles exiting and reentering the network.

8.3 Freeway Calibration Parameters

The primary freeway calibration parameters included driver behavior parameters related to car following and lane changing as well as connector look back distances. Ultimately, the driver behavior directly relates to the capacity of the links with which they are associated. For lower capacity sections, more conservative driver behavior parameters are used, and for higher capacity sections, more aggressive driver behavior. The driving behavior parameters for each type were varied to allow for increased headways, improved lane change (ramp merge cooperation) behavior, and overall driver aggressiveness. Additional freeway calibration parameters included per lane speed distribution profiles, as previously discussed, and lane utilization near high-volume ramp merges. A total of 14 link/driver behavior types were developed to model the freeway segments.

For all freeway driving behaviors, the Wiedemann 99 car following model was used. Low, mid, and high-capacity driver behavior parameters were developed for basic freeway, merge, diverge, and weave areas to achieve calibration of the field collected spot speed data. In addition to modifying the Wiedemann 99 car following model parameters, the look ahead distances and number of observed vehicles were also adjusted under the general car following parameters. **Table 8-2** and **Table 8-3** below summarize the adjusted or default “Freeway” car following and lane change driver behavior parameters used in Vissim to better replicate observed field conditions. The suggested ranges provided in Table 7-9 of the FDOT Traffic Analysis Handbook served as a starting point for calibration and any values that deviated from these ranges are noted in the tables. In general, only the CC4-CC9 car following parameters for the high-capacity driver behaviors deviated from the FDOT suggested ranges, which were to use the Vissim default values. Additional lane change parameters left at the software default values for all driver behaviors included waiting time before diffusion (60 seconds per FDOT guidelines), minimum headway (1.64 feet), and advanced merging.

Table 8-2 VISSIM Freeway Car Following Parameters

Freeway Driver Behavior	Look Ahead Distance (max)	Observed Vehicles	CC0	CC1	CC2	CC3	CC4	CC5	CC6	CC7	CC8	CC9

¹Values deviate from the FDOT suggested ranges in Table 7-9 of the Traffic Analysis Handbook.

A critical parameter in calibrating the freeway models is the connector lane change distance. This parameter controls where vehicles begin to react and change lanes in anticipation of downstream decisions. Starting with shorter distances and adjusting based on area specific driving behavior and lane utilization is critical in achieving the desired congestion levels in merge, diverge, and lane drop areas, especially in areas with multiple decision points. Connector lane change distance is a location specific function of driver behavior and can have a significant impact on traffic operations. Less aggressive drivers, for example, are more likely to respond earlier to guide signs regarding upcoming decision points. Adjustments to lane change distance are often needed to achieve the desired driver behavior, lane utilization, and level of congestion.

Another critical component in calibrating the freeway models was lane utilization at various ramp merges. While I-75 within the study area is not overly congested, the RITIS speed data indicated that slowdowns are present near multiple on-ramp merges due to significant lane utilization imbalances. **Figure 8-1** shows an example of the average weekday per lane volumes collected from RITIS on I-75 northbound at the SR 64 interchange during the September and October data collection period. The volumes in lane 1 (shown in blue) are significantly lower than the other two lanes as traffic moves over to accommodate the downstream merge. The resulting lane imbalance reduces the capacity of the freeway segment upstream of the merge and causes mainline speeds to drop.

A freeway driver behavior (Lane 1 Before Merge) was developed for this scenario using higher CCO (standstill distance), CC1 (headway time), and CC2 (following variation) car following parameters. A combination of per lane driver behaviors and blocked vehicle types on select links were used to encourage drivers to use the left-hand lanes. The use of blocked vehicle types does not prohibit traffic from remaining in lane 1, but vehicles are more apt to avoid that lane if there were opportunities to change lanes.

Freeway driver behaviors from the calibrated existing conditions models will be carried forward to the future year models. Any changes to link behavior types due to geometric improvements will be documented in the future conditions reports.

8.4 Arterial and Ramp Calibration Parameters

The primary arterial and ramp calibration parameters included driver behavior parameters related to car following and lane changing. A total of 4 link/driver behavior types were developed to model the arterial and ramp segments. For all arterial and ramp driving behaviors, the Wiedemann 74 car following model was used. Low, mid, and high-capacity driver behavior parameters were developed to achieve calibration of the field collected travel time data. Critical parameters in calibrating the arterial models are the additive and multiplicative part of safety distance, which are adjusted to increase or decrease the saturation flow rate. The look ahead distances and number of observed vehicles were also adjusted under the general car following parameters. **Table 8-4** below summarizes the adjusted or default “Urban” car-following and lane-change driver behavior parameters used in Vissim to better replicate observed field conditions.

Arterial and ramp driver behaviors from the calibrated existing conditions models will be carried forward to the future year models. Any changes to link behavior types due to geometric improvements will be documented in the future conditions reports.

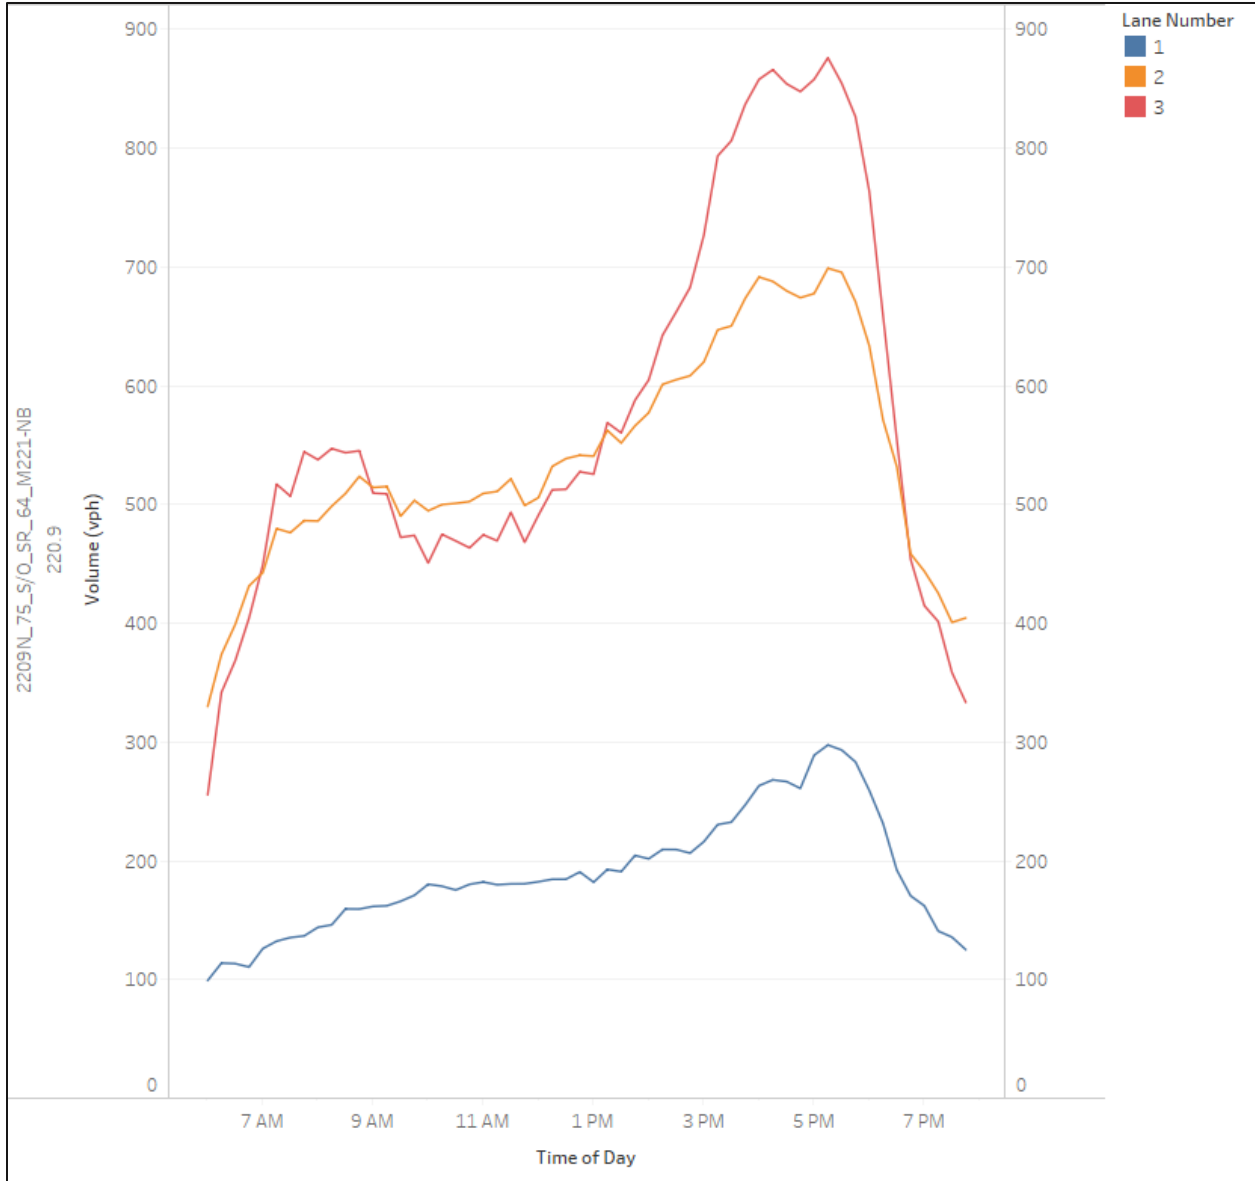

Figure 8-1 I-75 Northbound RITIS Volumes Per Lane at I-75/SR 64 Interchange

The subarea Vissim models for each interchange area were calibrated using Bluetooth travel time data. The travel time data was collected over a 7-day period and was used to determine the average weekday (Tuesday-Thursday) travel times for the AM and PM peak hours. Any outlier data that appeared to be the result of incidents or other unknown factors was removed from the average travel time calculation. Most of the travel time data was collected between late August 2019 and mid October 2019 except for the US 41 and Laurel Road interchanges. Due to issues with the original deployment of the Bluetooth sensors, the US 41 interchange was collected in February 2020 and the Laurel Road interchange was collected in December 2019. Although the travel time data was not collected at the same time as the count data, both interchanges experience very little congestion and the different time periods during which data was collected had little impact on calibration.

Table 8-4 Vissim Urban Driver Behavior Parameters

Urban Driving Behavior		Units	Default	Lower Capacity	Mid Capacity	Mid to High Capacity	Higher Capacity
Car Following Parameters							
W74	Average Standstill Distance	(ft)	6.56	6.56	6.56	6.56	6.56

Trailing	Maximum Deceleration	(ft/s ²)	-9.84	-12	-12	-12	-12
	-1 ft/s ² per distance	(ft)	100.00	100	100	100	100
	Accepted Deceleration	(ft/s ²)	-3.28	-3.28	-3.28	-3.28	-3.28
Other Parameters	Waiting Time before Diffusion	(s)	60	60	60	60	60
	Min Headway (Front/Rear)	(ft)	1.64	1.64	1.64	1.64	1.64
	Safety Distance Factor	--	0.60	0.60	0.60	0.60	0.60
	Max Decel for Cooperative Braking	(ft/s ²)	-9.84	-12	-12	-12	-12
	Advanced Merging	(Y/N)	Y	Y	Y	Y	Y
	Cooperative Lane Change	(Y/N)	N	Y	Y	Y	Y
	Maximum Speed Difference	(mph)	6.71	10	7	7	4
	Maximum Collision Time	(s)	10	18	10	10	5

In addition to modifying global driver behavior parameters, localized adjustments to lane change distances and other network elements were required to achieve the desired levels of congestion and meet volume and travel time targets. Key adjustments included the following:

- Lane change distances were modified, as needed, based on animation observation to achieve a better replication of field-measured or field-observed lane utilization, travel times, and overall congestion levels.
- Desired speed distributions for roadway segments were initially coded based on the posted speed limit and adjusted +/- 5 mph in areas where travel times indicated slower or faster desired speeds. Turning speeds were also adjusted, including per lane speeds for cars and trucks, to replicate the throughput volumes observed in the field.
- Priority rules were used to avoid blocking of intersections in areas that experienced queue spillback. These priority rules improved the driver behavior in these areas to more accurately reflect field observed gap acceptance and saturated driving conditions in the area.

9.0 Interchange Subarea Calibration Results

The existing conditions subarea Vissim models for each interchange area were calibrated to field measured travel times and balanced traffic volumes. Visual audits were also performed to check the consistency of the model with field conditions. While a peak period analysis was performed using one shoulder hour each before and after the peak hour, the calibration results discussed in the following subsections are for the peak hour only. The calibration parameters that were developed and used for the peak hour were also assumed to be appropriate for shoulder hour conditions. The calibration results discussed below are based on the average of ten simulation runs and the simulated traffic volumes are based on total volume (sum of all turning movements) at the intersections. Individual movement results for each intersection are provided in **Appendix J**.

Overall, the calibration of the existing conditions subarea Vissim models for each interchange area produced simulation output that replicated existing traffic operations and field-observed driver behavior for both the AM and PM peak period. Calibration was met for every volume and GEH target, for both individual turning movements and overall intersections, and all travel time segments.

9.1 Moccasin Wallow Road

A comparison of the AM and PM peak hour modeled traffic volumes and balanced field-collected volumes for each intersection are provided in **Table 9-1** and **Table 9-2**. As shown below, the AM and PM peak hour traffic volumes, as measured in the Vissim simulation models, correlate well with the balanced field-collected volumes, with a calculated GEH of 0.6 or less for all intersections. All individual turning movements meet both the volume criteria and GEH thresholds, with a calculated GEH of 2.0 or less in the AM peak hour and 1.2 or less in the PM peak hour for all movements. The sum of all modeled intersection volumes is within 0.7 percent of the sum of all intersection demand volumes in both the AM and PM peak hours.

Table 9-1 Moccasin Wallow Road Traffic Volume Summary – AM Peak Hour

Intersection	Measured Volume	Simulated Volume	GEH	Difference		Volume Measure	Meets Targets?
				vph	%		
Gateway Boulevard	1528	1512	0.4	-16	-1.0%	+/- 15%	Yes

71st Avenue	727	721	0.2	-6	-0.8%	+/- 15%	Yes

A comparison of the AM and PM peak hour modeled travel times and field-collected travel times for Moccasin Wallow Road are shown below in **Table 9-3**. With all field-measured travel times being less than 7 minutes, the applicable calibration target used was simulated travel times within 1 minute of the field-measured travel times as opposed to the 15 percent threshold. As shown below, the average travel times, estimated using Vissim, correlate well with the travel times collected in the field for both the AM and PM peak hours.

Table 9-3 Moccasin Wallow Road Travel Time Summary

Travel Time Segments			Field Measured	Calibrated Model - VISSIM			Meets Target?
Peak Hour	Direction	Segment	Travel Time (mins)	Travel Time (mins)	Difference		
					minutes	%	
AM	EB	West of Gillette Dr to East of NB Ramp	0.72	0.90	0.18	25.7%	Yes
	WB	East of NB Ramp to West of Gillette Dr	0.59	1.03	0.44	74.5%	Yes
PM	EB	West of Gillette Dr to East of NB Ramp	0.72	0.88	0.15	21.4%	Yes
	WB	East of NB Ramp to West of Gillette Dr	0.54	1.01	0.47	87.8%	Yes

9.2 I-275 at US 41

A comparison of the AM and PM peak hour modeled traffic volumes and balanced field-collected volumes for each intersection are provided in **Table 9-4** and **Table 9-5**. As shown below, the AM and PM peak hour traffic volumes, as measured in the Vissim simulation models, correlate well with the balanced field-collected volumes, with a calculated GEH of 0.4 or less for all intersections. All individual turning movements meet both the volume criteria and GEH thresholds, with a calculated GEH of 1.1 or less in the AM peak hour and 0.7 or less in the PM peak hour for all movements. The sum of all modeled intersection volumes is 0.3 and 0.4 percent of the sum of all intersection demand volumes in the AM and PM peak hours, respectively.

9.3 US 301

A comparison of the AM and PM peak hour modeled traffic volumes and balanced field-collected volumes for each intersection are provided in **Table 9-7** and **Table 9-8**. As shown below, the AM and PM peak hour traffic volumes, as measured in the Vissim simulation models, correlate well with the balanced field-collected volumes, with a calculated GEH of 0.5 or less for all intersections. All individual turning movements meet both the volume criteria and GEH thresholds, with a calculated GEH of 1.4

or less in both the AM and PM peak hours for all movements. The sum of all modeled intersection volumes is within 0.2 and 0.5 percent of the sum of all intersection demand volumes in the AM and PM peak hours, respectively.

A comparison of the AM and PM peak hour modeled travel times and field-collected travel times for SR 64 are shown below in **Table 9-12**. With all field-measured travel times being less than 7 minutes, the applicable calibration target used was simulated travel times within 1 minute of the field-measured travel times as opposed to the 15 percent threshold. As shown below, the average travel times, estimated using Vissim, correlate well with the travel times collected in the field for both the AM and PM peak hours.

Table 9-12 SR 64 Travel Time Summary

Travel Time Segments			Field Measured	Calibrated Model - VISSIM			Meets Target?
Peak Hour	Direction	Segment	Travel Time (mins)	Travel Time (mins)	Difference		
					minutes	%	
AM	EB	West of 62nd St to East of Grand Harbour Pkwy	1.86	2.24	0.38	20.7%	Yes
	WB	East of Grand Harbour Pkwy to West of 62nd St	2.81	2.62	-0.18	6.5%	Yes
PM	EB	West of 62nd St to East of Grand Harbour Pkwy	2.03	2.40	0.37	18.2%	Yes
	WB	East of Grand Harbour Pkwy to West of 62nd St	2.84	2.86	0.02	0.6%	Yes

9.5 SR 70

A comparison of the AM and PM peak hour modeled traffic volumes and balanced field-collected volumes for each intersection are provided in **Table 9-13** and **Table 9-14**. As shown below, the AM and PM peak hour traffic volumes, as measured in the Vissim simulation models, correlate well with the balanced field-collected volumes, with a calculated GEH of 1.1 or less for all intersections. All individual turning movements meet both the volume criteria and GEH thresholds, with a calculated GEH of 0.9 or less in both the AM and PM peak hours for all movements. The sum of all modeled intersection volumes is within 0.6 and 0.4 percent of the sum of all intersection demand volumes in the AM and PM peak hours, respectively.

	WB	East of Oak Run Dr to West of Creekwood Blvd	4.21	3.79	-0.43	10.1%	Yes

9.6 University Parkway

A comparison of the AM and PM peak hour modeled traffic volumes and balanced field-collected volumes for each intersection are provided in **Table 9-16** and **Table 9-17**. As shown below, the AM and PM peak hour traffic volumes, as measured in the Vissim simulation models, correlate well with the balanced field-collected volumes, with a calculated GEH of 0.9 or less for all intersections. All individual turning movements meet both the volume criteria and GEH thresholds, with a calculated GEH of 2.0 or less in the AM peak hour and 1.4 or less in the PM peak hour for all movements. The sum of all

modeled intersection volumes is within 0.7 and 0.3 percent of the sum of all intersection demand volumes in the AM and PM peak hours, respectively.

9.7 SR 780 (Fruitville Road)

A comparison of the AM and PM peak hour modeled traffic volumes and balanced field-collected volumes for each intersection are provided in **Table 9-19** and **Table 9-20**. As shown below, the AM and PM peak hour traffic volumes, as measured in the Vissim simulation models, correlate well with the balanced field-collected volumes, with a calculated GEH of 0.7 or less for all intersections. All individual turning movements meet both the volume criteria and GEH thresholds, with a calculated GEH of 0.8 or less in the AM peak hour and 0.7 or less in the PM peak hour for all movements. The sum of all modeled intersection volumes is within 0.5 and 0.0 percent of the sum of all intersection demand volumes in the AM and PM peak hours, respectively.

Table 9-19 SR 780 (Fruitville Road) Traffic Volume Summary – AM Peak Hour

	WB	East of Coburn Rd to West of Cattlemen Rd	2.78	3.08	0.30	10.9%	Yes

9.8 SR 758 (Bee Ridge Road)

A comparison of the AM and PM peak hour modeled traffic volumes and balanced field-collected volumes for each intersection are provided in **Table 9-22** and **Table 9-23**. As shown below, the AM and PM peak hour traffic volumes, as measured in the Vissim simulation models, correlate well with the balanced field-collected volumes, with a calculated GEH of 1.4 or less for all intersections. All individual turning movements meet both the volume criteria and GEH thresholds, with a calculated GEH of 1.1 or less in the AM peak hour and 1.2 or less in the PM peak hour for all movements. The sum of all modeled intersection volumes is within 1.6 and 0.7 percent of the sum of all intersection demand volumes in the AM and PM peak hours, respectively.

9.9 SR 72 (Clark Road)

A comparison of the AM and PM peak hour modeled traffic volumes and balanced field-collected volumes for each intersection are provided in **Table 9-25** and **Table 9-26**. As shown below, the AM and PM peak hour traffic volumes, as measured in the Vissim simulation models, correlate well with the balanced field-collected volumes, with a calculated GEH of 1.1 or less for all intersections. All individual turning movements meet both the volume criteria and GEH thresholds, with a calculated GEH of 0.8 or less in the AM peak hour and 1.4 or less in the PM peak hour for all movements. The sum of all modeled intersection volumes is within 1.3 and 1.1 percent of the sum of all intersection demand volumes in the AM and PM peak hours, respectively.

Hummingbird Avenue	1490	1475	0.4	-15	-1.0%	+/- 15%	Yes

A comparison of the AM and PM peak hour modeled travel times and field-collected travel times for Clark Road are shown below in **Table 9-27**. With all field-measured travel times being less than 7 minutes, the applicable calibration target used was simulated travel times within 1 minute of the field-measured travel times as opposed to the 15 percent threshold. As shown below, the average travel times, estimated using Vissim, correlate well with the travel times collected in the field for both the AM and PM peak hours.

Table 9-27 SR 72 (Clark Road) Travel Time Summary

Travel Time Segments			Field Measured	Calibrated Model - VISSIM			Meets Target?
Peak Hour	Direction	Segment		Travel Time (mins)	Travel Time (mins)	Difference	
			minutes			%	
AM	EB	West of Gantt Rd to East of Hummingbird Ave	2.34	2.20	-0.14	5.9%	Yes
	WB	East of Hummingbird Ave to West of Gantt Rd	4.31	3.63	-0.68	15.7%	Yes
PM	EB	West of Gantt Rd to East of Hummingbird Ave	1.92	2.14	0.22	11.5%	Yes
	WB	East of Hummingbird Ave to West of Gantt Rd	3.09	3.71	0.62	20.2%	Yes

9.10 SR 681

A comparison of the AM and PM peak hour modeled traffic volumes and balanced field-collected volumes for the SR 681 and Honore Avenue intersection are provided in **Table 9-28** and **Table 9-29**. As shown below, the AM and PM peak hour traffic volumes, as measured in the Vissim simulation models, correlate well with the balanced field-collected volumes, with a calculated GEH of 0.2 or less for the Honore Avenue intersection. All individual turning movements meet both the volume criteria and GEH thresholds, with a calculated GEH of 0.9 or less in the AM peak hour and 1.0 or less in the PM peak hour for all movements. The sum of the modeled intersection volumes is within 0.5 and 0.3 percent of the sum of the intersection demand volumes in the AM and PM peak hours, respectively. Because the SR 681 interchange includes only one intersection adjacent to the free flow ramps at I-75, no travel time comparison was made as part of calibration.

Table 9-28 SR 681 Traffic Volume Summary – AM Peak Hour

Intersection	Measured Volume	Simulated Volume	GEH	Difference		Volume Measure	Meets Targets?
				vph	%		
Honore Avenue	1851	1842	0.2	-9	-0.5%	+/- 15%	Yes

				vph	%		
Honore Avenue	1712	1707	0.1	-5	-0.3%	+/- 15%	Yes

9.11 Laurel Road

A comparison of the AM and PM peak hour modeled traffic volumes and balanced field-collected volumes for each intersection are provided in **Table 9-30** and **Table 9-31**. As shown below, the AM and PM peak hour traffic volumes, as measured in the Vissim simulation models, correlate well with the balanced field-collected volumes, with a calculated GEH of 0.7 or less for all intersections. All individual turning movements meet both the volume criteria and GEH thresholds, with a calculated GEH of 1.4 or less in both the AM and PM peak hours for all movements. The sum of all modeled intersection volumes is within 0.3 percent of the sum of all intersection demand volumes in both the AM and PM peak hours.

Table 9-30 Laurel Road Traffic Volume Summary – AM Peak Hour

Intersection	Measured Volume	Simulated Volume	GEH	Difference		Volume Measure	Meets Target?
				vph	%		
Twin Laurel Boulevard	1336	1346	0.3	10	0.7%	+/- 15%	Yes

9.12 Jacaranda Boulevard

A comparison of the AM and PM peak hour modeled traffic volumes and balanced field-collected volumes for each intersection are provided in **Table 9-33** and **Table 9-34**. As shown below, the AM and PM peak hour traffic volumes, as measured in the Vissim simulation models, correlate well with the balanced field-collected volumes, with a calculated GEH of 0.6 or less for all intersections. All individual turning movements meet both the volume criteria and GEH thresholds, with a calculated GEH of 0.9 or less in the AM peak hour and 1.4 or less in the PM peak hour for all movements. The sum of all modeled intersection volumes is within 0.8 and 0.6 percent of the sum of all intersection demand volumes in the AM and PM peak hours, respectively.

A comparison of the AM and PM peak hour modeled travel times and field-collected travel times for Jacaranda Boulevard are shown below in **Table 9-35**. With all field-measured travel times being less than 7 minutes, the applicable calibration target used was simulated travel times within 1 minute of the field-measured travel times as opposed to the 15 percent threshold. As shown below, the average travel times, estimated using Vissim, correlate well with the travel times collected in the field for both the AM and PM peak hours.

Table 9-35 Jacaranda Boulevard Travel Time Summary

Travel Time Segments			Field Measured	Calibrated Model - VISSIM			Meets Target?
Peak Hour	Direction	Segment		Travel Time (mins)	Travel Time (mins)	Difference

	SB	North of Snyder Dr to South of Oak Heritage Dr	2.94	2.31	-0.63	21.4%	Yes

9.13 N River Road

A comparison of the AM and PM peak hour modeled traffic volumes and balanced field-collected volumes for each intersection are provided in **Table 9-36** and **Table 9-37**. As shown below, the AM and PM peak hour traffic volumes, as measured in the Vissim simulation models, correlate well with the

balanced field-collected volumes, with a calculated GEH of 0.1 or less for all intersections. All individual turning movements meet both the volume criteria and GEH thresholds, with a calculated GEH of 0.9 or less in the AM peak hour and 0.5 or less in the PM peak hour for all movements. The sum of all modeled intersection volumes is within 0.2 percent of the sum of all intersection demand volumes in both the AM and PM peak hours.

10.0 I-75 Subarea Calibration Results

The existing conditions subarea Vissim models for the I-75 mainline were calibrated to field measured speed data and balanced traffic volumes. Visual audits were also performed to check the consistency of the model with field conditions. Due to the length of the I-75 corridor (39.3 miles) and the time it takes to traverse the entire network, the seeding period for the I-75 subarea and combined model in the AM peak period used a combination of volumes from the first shoulder hour. With such low volumes occurring during the 5:30 AM to 6:30 AM seeding period, traffic volumes recorded in the model during the AM peak hour were too low at the edges of the network. Higher traffic volumes during the seeding period were required to achieve the desired model throughput during the peak hour. The seeding period volumes during the PM peak period were closer to the first shoulder hour volumes and no adjustments were needed to achieve the calibration targets.

The calibration results discussed below are based on the average of ten simulation runs. Overall, the calibration of the existing conditions subarea Vissim models for the I-75 mainline produced simulation output that replicated existing traffic operations and field observed driver behavior for both the AM and PM peak period. Calibration was met for 100 percent of volume and GEH targets for all merge and diverge locations during both the peak hour and overall analysis period. In addition, more than 96 percent of the average hourly and 15-minute speeds are within the +/- 10 mph calibration target for both the AM and PM peak periods.

10.1 Volume Calibration Results

A comparison of the peak hour modeled traffic volumes and balanced field-collected volumes at each merge and diverge location are provided in **Table 10-1** and **Table 10-2** for the AM peak hour and **Table 10-3** and **Table 10-4** for the PM peak hour. Since the I-275 and US 41 interchange is included in the area of influence for the study area, a comparison of the peak hour modeled traffic volumes and balanced field-collected volumes at each merge and diverge location at the US 41 interchange are provided in **Table 10-5** and **Table 10-6** for the AM and PM peak hours. While a peak period analysis was performed using one shoulder hour each before and after the peak hour, the calibration results shown below are for the peak hour only. The calibration parameters that were developed and used for the peak hour were also assumed to be appropriate for shoulder hour conditions. Calibration results for the entire three-hour analysis period are provided in **Appendix J**.

As shown below, the AM and PM peak hour mainline and ramp volumes, as measured in the Vissim simulation models, correlate well with the balanced traffic demand volumes, with a calculated GEH of 2.4 or less in the AM peak hour and 0.9 or less in the PM peak hour for all merge and diverge locations on I-75 and I-275. All locations meet both the volume criteria and GEH thresholds and the sum of all volumes is within 0.2 and 0.6 percent of the sum of all demand volumes in the AM and PM peak hours, respectively.

It should be noted that the simulated volumes in the second shoulder hour are generally higher than the peak hour due to the length of the corridor and the time it takes to traverse the entire network. Traffic that did not reach its destination at the end of the peak hour gets recorded in the shoulder hour, resulting in GEH values of up to 3.4 in the AM peak period and 5.5 in the PM peak period. The combined traffic volumes for the entire three-hour analysis period have a calculated GEH of 2.6 or less and are within a maximum of 1.1 percent of all demand volumes.

10.2 Speed Calibration Results

Speed data for calibration on I-75 was obtained from RITIS. RITIS maintains all FDOT District One detector data in addition to several other FDOT Districts. The RITIS database was used to calculate average 15-minute, weekday speeds (Tuesday- Thursday) between September and October 2019, which is consistent with the data collection period for the project. A total of 151 RITIS detectors (77 northbound and 74 southbound) within the project limits were used for calibration.

A comparison of the AM and PM peak period modeled speeds and RITIS detector speeds for I-75 are shown below in **Table 10-7** and **Table 10-8** for the AM peak period and **Table 10-9** and **Table 10-10** for the PM peak period. Average hourly speeds are provided for the three-hour analysis period. Average speeds in 15-minute intervals are provided in **Appendix J**. As previously noted, portions of the I-75 mainline are currently under construction between University Parkway and SR 64 and construction was ongoing during data collection. The existing conditions Vissim models used the pre-construction configuration on I-75 and the simulated speeds are not directly comparable to the RITIS speeds in the areas that were impacted by construction. In addition to the mainline construction, the SR 70 interchange is also currently under construction and improvements to the SR 64 interchange were recently completed. The SR 64 and SR 70 interchanges were in varying stages of construction during data collection that could impact speeds on I-75. Construction primarily affected southbound I-75 in the AM peak hour and northbound I-75 in the PM peak hour.

As shown below, the AM and PM average hourly speeds, estimated using Vissim, correlate well with the RITIS detector speed data in the areas that were not impacted by construction. More than 99 percent of the I-75 northbound and I-75 southbound average hourly speeds are within the +/- 10 mph calibration target for both the AM and PM peak periods. The average 15-minute speeds also meet calibration targets for over 98 percent of all periods, with 100 percent of the average 15-minute speeds within +/- 15 mph of the RITIS detector speeds. Based on the results of the speed calibration, the average speeds on I-75 in the subarea Vissim models are a good representation of the existing speeds that were obtained from the RITIS detectors.

11.0 Combined Model Calibration Results

The calibrated subarea models were merged into a single model by combining the individual interchange models with the I-75 mainline model. The combined models were verified for calibration and then used for the analysis of existing conditions. The calibration results for the combined models are based on the average of ten simulation runs and a summary of the results is discussed below. Overall, the calibration of the existing conditions combined Vissim models produced simulation output that replicated existing traffic operations and field observed driver behavior for each interchange area and the I-75 mainline for both the AM and PM peak period. Calibration was met for 100 percent of peak hour volume and GEH targets for all intersections, as well as all merge and diverge locations during both the peak hour and overall analysis period. In addition, more than 96 percent of the average hourly and 15-minute speeds are within the +/- 10 mph calibration target for both the AM and PM peak periods.

11.1 Interchange Volume Calibration Results

A comparison of the AM and PM peak hour modeled traffic volumes and balanced field-collected volumes for each intersection are provided in **Table 11-1** and **Table 11-2**. While a peak period analysis was performed using one shoulder hour each before and after the peak hour, the calibration results are for the peak hour only. The traffic volume results shown below are based on total volume (sum of all turning movements) at the intersections. Individual movement results for each intersection are provided in **Appendix K**. As shown below, the AM and PM peak hour traffic volumes, as measured in the combined Vissim simulation models, correlate well with the balanced field-collected volumes, with a calculated GEH of 1.7 or less in the AM peak hour and 1.3 or less in the PM peak hour for all intersections. The sum of all modeled intersection volumes is within 1.0 and 0.7 percent of the sum of all intersection demand volumes in the AM and PM peak hours, respectively.

11.2 Interchange Travel Time Calibration Results

A comparison of the AM and PM peak hour modeled travel times and field-collected travel times for all interchanges in the combined Vissim model are shown below in **Table 11-3** for the AM peak hour and **Table 11-4** for the PM peak hour. With all field-measured travel times being less than 7 minutes, the applicable calibration target used was simulated travel times within 1 minute of the field-measured travel times as opposed to the 15 percent threshold. As shown below, the average travel times, estimated using Vissim, correlate well with the travel times collected in the field for both the AM and PM peak hours. Although all modeled travel times meet the calibration targets, the eastbound travel time segment on University Parkway in the AM peak hour and the westbound travel time segment on University Parkway in the PM peak hour are both at the 1-minute threshold. The field data at this location included minimum travel times of less than 30 seconds for a nearly 1.5-mile segment, which may indicate that the travel time data is unreliable. No outliers were reported in the field data and no unusual behavior was observed in the simulation models. The reported travel times are therefore considered appropriate for the corridor.

11.3 I-75 Mainline Volume Calibration Results

A comparison of the peak hour modeled traffic volumes and balanced field-collected volumes at each merge and diverge location on I-75 are provided in **Table 11-5** and **Table 11-6** for the AM peak hour and **Table 11-7** and **Table 11-8** for the PM peak hour. A comparison of the peak hour modeled traffic volumes and balanced field-collected volumes at each merge and diverge location on I-275 at the US 41 interchange are provided in **Table 11-9** and **Table 11-10** for the AM and PM peak hours. While a peak period analysis was performed using one shoulder hour each before and after the peak hour, the calibration results shown below are for the peak hour only. Calibration results for the entire three-hour analysis period are provided in **Appendix K**.

As shown below, the AM and PM peak hour mainline and ramp volumes, as measured in the combined Vissim simulation models, correlate well with the balanced traffic demand volumes, with a calculated GEH of 1.8 or less in the AM peak hour and 1.6 or less in the PM peak hour for all merge and diverge locations on I-75 and I-275. All locations meet both the volume criteria and GEH thresholds and the sum of all volumes is within 1.2 percent of the sum of all demand volumes in both the AM and PM peak hours.

It should be noted that the simulated volumes in the second shoulder hour are generally higher than the peak hour due to the length of the corridor and the time it takes to traverse the entire network. Traffic that did not reach its destination at the end of the peak hour gets recorded in the shoulder hour, resulting in GEH values of up to 4.1 in the AM peak period and 7.4 in the PM peak period. The combined traffic volumes for the entire three-hour analysis period have a calculated GEH of less than 3.0 and are within a maximum of 1.3 percent of all demand volumes.

11.4 I-75 Mainline Speed Calibration Results

A comparison of the AM and PM peak period modeled speeds and RITIS detector speeds for I-75 are shown below in **Table 11-11** and **Table 11-12** for the AM peak period and **Table 11-13** and **Table 11-14** for the PM peak period. Average hourly speeds are provided for the three-hour analysis period. Average speeds in 15-minute intervals are provided in **Appendix K**. As previously noted, portions of the I-75 mainline are currently under construction between University Parkway and SR 64 and construction was ongoing during data collection. The existing conditions Vissim models used the pre-construction configuration on I-75 and the simulated speeds are not directly comparable to the RITIS speeds in the areas that were impacted by construction. In addition to the mainline construction, the SR 70 interchange is also currently under construction and improvements to the SR 64 interchange were recently completed. The SR 64 and SR 70 interchanges were in varying stages of construction during data collection that could impact speeds on I-75. Construction primarily affected southbound I-75 in the AM peak hour and northbound I-75 in the PM peak hour.

As shown below, the AM and PM average hourly speeds, estimated using Vissim, correlate well with the RITIS detector speed data in the areas that were not impacted by construction. More than 99 percent of the I-75 northbound and the I-75 southbound average hourly speeds are within the +/- 10 mph calibration target for both the AM and PM peak periods. The average 15-minute speeds also meet calibration targets for over 98 percent of all periods, with nearly 100 percent of the average 15-minute speeds within +/- 15 mph of the RITIS detector speeds. Based on the results of the speed calibration, the average speeds on I-75 in the combined Vissim models are a good representation of the existing speeds that were obtained from the RITIS detectors.

12.0 Existing Year Traffic Analysis Results

12.1 Intersection Analysis

An operational analysis of the existing conditions at each interchange area was performed using the calibrated combined Vissim model. While a peak period analysis was performed using one shoulder hour each before and after the peak hour, the overall intersection delay and LOS results discussed in the following subsections are for the peak hour only. The analysis results discussed below are based on the average of ten simulation runs. Detailed operational results for each interchange area, including delay, LOS, and queuing for all movements, is provided in **Appendix L**.

In Vissim, the intersection LOS is computed from a microsimulation analysis and is therefore reported as an “estimated LOS.” Vissim quantifies overall intersection delays more realistically than typical equation-based HCM methods because it tracks individual vehicle movements and interactions. The estimated LOS for existing conditions is based on HCM criteria and thresholds for signalized and unsignalized intersections. The overall intersection delay and LOS for signalized intersections is based on the total control delay of all movements. The overall intersection delay and LOS for unsignalized intersections is based on the worst stop-controlled movement per HCM standards.

12.1.1 Moccasin Wallow Road

A summary of overall intersection delay and LOS for the existing AM and PM peak hour conditions is provided in **Table 12-1** for Moccasin Wallow Road. As shown below, the I-75 ramp terminal intersections are operating at LOS C in both the AM and PM peak hours except for the I-75 northbound terminal in the AM peak hour, which is operating at LOS E. Both ramp terminals are unsignalized and the intersection LOS is based on the worst stop-controlled movement, which is the off-ramp left-turn movement. The adjacent unsignalized intersections are operating at LOS E or better and the signalized intersection at Gateway Boulevard is operating at LOS B in both peak hours.

Table 12-1 Moccasin Wallow Road Peak Hour Vissim Analysis Summary

Intersection	Traffic Control	AM Peak		PM Peak	
		Delay (sec/veh)	Estimated LOS	Delay (sec/veh)	Estimated LOS
Moccasin Wallow Rd & Gateway Blvd	Signalized	17.9	B	12.8	B
Moccasin Wallow Rd & Gillette Dr	Unsignalized	3.1	A	7.1	A
Moccasin Wallow Rd & I-75 SB Ramps	Unsignalized	22.4	C	16.0	C
Moccasin Wallow Rd & I-75 NB Ramps	Unsignalized	36.5	E	17.1	C
Moccasin Wallow Rd & Buffalo Rd	Unsignalized	46.2	E	18.2	C
Moccasin Wallow Rd & 71st Ave	Unsignalized	15.6	E	11.0	C

12.1.2 I-275 at US 41

A summary of overall intersection delay and LOS for the existing AM and PM peak hour conditions is provided in **Table 12-2** for the I-275 and US 41 interchange. As shown below, the I-275 northbound ramp terminal is operating at LOS B in both peak hours, while the I-275 southbound ramp terminal is operating at LOS E in the AM peak hour and LOS F in the PM peak hour. The southbound ramp terminal is unsignalized and the intersection LOS is based on the worst stop-controlled movement, which is the

off-ramp left-turn movement. The southbound off-ramp left-turn movement experience delays of over 3 minutes trying to turn left onto northbound US 41 and queuing of over 1,100 feet. The adjacent unsignalized intersection at 85th Street is also operating at LOS F in the AM peak hour and the signalized intersection at 73rd Street is operating at LOS C in both peak hours.

Table 12-2 I-275 at US 41 Peak Hour Vissim Analysis Summary

Intersection	Traffic Control	AM Peak		PM Peak	
		Delay (sec/veh)	Estimated LOS	Delay (sec/veh)	Estimated LOS
US 41 & 85th St	Unsignalized	54.5	F	30.1	D
US 41 & I-275 NB Ramps	Signalized	16.2	B	11.6	B
US 41 & I-275 SB Ramps	Unsignalized	47.4	E	203.4	F
US 41 & 73rd St	Signalized	24.6	C	25.9	C

12.1.3 US 301

A summary of overall intersection delay and LOS for the existing AM and PM peak hour conditions is provided in **Table 12-3** for US 301. As shown below, all study area intersections are operating at LOS D or better except for the unsignalized intersection at 18th Street, which is operating at LOS E in the PM peak hour. Multiple movements at the adjacent signalized intersections are operating at LOS E or F, but the through movements on US 301 are operating at LOS C or better. At the I-75 ramp terminal intersections, the off-ramp left-turn movements are operating at LOS E and the eastbound left turn at both ramp terminal intersections is operating at LOS E or F, but overall operations are LOS C in both peak hours.

Table 12-3 US 301 Peak Hour Vissim Analysis Summary

Intersection	Traffic Control	AM Peak		PM Peak	
		Delay (sec/veh)	Estimated LOS	Delay (sec/veh)	Estimated LOS
US 301 and 51st Ave	Signalized	21.9	C	16.7	B
US 301 and I-75 SB Ramps	Signalized	23.1	C	26.9	C
US 301 and I-75 NB Ramps	Signalized	22.1	C	30.4	C
US 301 and 60th Ave	Signalized	39.9	D	37.9	D
US 301 and Kmart Driveway	Unsignalized	14.9	B	26.1	D
US 301 and 18th St	Unsignalized	13.9	B	45.5	E

12.1.4 SR 64

A summary of overall intersection delay and LOS for the existing AM and PM peak hour conditions is provided in **Table 12-4** for SR 64. As shown below, all study area intersections are operating at LOS D or better except for the unsignalized crossing at 62nd Street, which is operating at LOS F in both the AM and PM peak hours. The failing movement at this intersection is the westbound left turn, which has difficulty finding gaps in traffic on eastbound SR 64. Construction at the interchange was recently completed and the analysis results are reflective of these improvements with both ramp terminal intersections operating at LOS C or better and no queuing that exceeds available storage.

Table 12-4 SR 64 Peak Hour Vissim Analysis Summary

Intersection	Traffic Control	AM Peak		PM Peak	
		Delay (sec/veh)	Estimated LOS	Delay (sec/veh)	Estimated LOS
SR 64 & 62nd St	Unsignalized	62.6	F	71.6	F
SR 64 & 65th St	Unsignalized	22.6	C	33.9	D
SR 64 & 66th St	Signalized	21.7	C	24.0	C
SR 64 & I-75 SB Ramps	Signalized	15.7	B	15.3	B
SR 64 & I-75 NB Ramps	Signalized	25.9	C	27.5	C
SR 64 & Grand Harbour Pkwy	Signalized	10.2	B	14.7	B

12.1.5 SR 70

A summary of overall intersection delay and LOS for the existing AM and PM peak hour conditions is provided in **Table 12-5** for SR 70. As shown below, all study area intersections are operating at LOS D or better except for the unsignalized intersection at Lena Road, which is operating at LOS E in the AM and PM peak hours. At the I-75 ramp terminal intersections, the off-ramp left-turn movements are operating at LOS E, and the eastbound left-turn movement at the northbound ramp terminal intersection is operating at LOS F in the AM peak hour and LOS E in the PM peak hour, but overall operations are LOS C or better. Although the eastbound left-turn movement is operating at LOS E or F in the AM and PM peak hours, respectively, this is primarily the result of signal timing and queuing does not exceed the available storage.

Table 12-5 SR 70 Peak Hour Vissim Analysis Summary

Intersection	Traffic Control	AM Peak		PM Peak	
		Delay (sec/veh)	Estimated LOS	Delay (sec/veh)	Estimated LOS
SR 70 & Creekwood Blvd	Signalized	34.2	C	39.1	D
SR 70 & 73rd Ln	Unsignalized	20.9	C	22.0	C
SR 70 & I-75 SB Ramps	Signalized	17.5	B	20.4	C
SR 70 & I-75 NB Ramps	Signalized	21.2	C	24.7	C
SR 70 & Lena Rd	Unsignalized	47.3	E	35.8	E
SR 70 & 87th St	Signalized	22.4	C	33.4	C
Creekwood Blvd & 52nd Pl	Unsignalized	10.5	B	17.9	C
Tara Blvd & 55th Ave	Unsignalized	7.6	A	7.6	A

12.1.6 University Parkway

A summary of overall intersection delay and LOS for the existing AM and PM peak hour conditions is provided in **Table 12-6** for University Parkway. As shown below, the I-75 ramp terminal intersections are operating at LOS D or better, while the adjacent intersections at Cattlemen Road and Market Street are operating at LOS E in the PM peak hour. Multiple movements are also operating at LOS E or F at the Town Center Parkway intersection, including the westbound through movement (LOS F) in the PM

peak hour, which is the result of queue spillback from the Market Street intersection. The unsignalized driveway on University Parkway at Lakewood Ranch, as well as the unsignalized intersection at Cooper Creek Boulevard and Tourist Center Drive, are operating at LOS F in the PM peak hour. The LOS F operations are based on the delay for the free flow westbound and southbound through movements, which are impacted by downstream queuing. Queuing in the eastbound direction at Market Street (predominately from the eastbound left-turn movement) spills back to the I-75 northbound ramp terminal, resulting in over 1,600 feet of queuing on the off-ramp that exceeds the available storage.

Table 12-6 University Parkway Peak Hour Vissim Analysis Summary

Intersection	Traffic Control	AM Peak		PM Peak	
		Delay (sec/veh)	Estimated LOS	Delay (sec/veh)	Estimated LOS
University Pkwy & Cattlemen Rd	Signalized	37.1	D	61.8	E
University Pkwy & I-75 SB Ramps	Signalized	39.5	D	29.0	C
University Pkwy & I-75 NB Ramps	Signalized	43.5	D	33.3	C
University Pkwy & Market Street	Signalized	51.3	D	64.0	E
University Pkwy & Lakewood Ranch Driveway	Unsignalized	19.6	C	67.9	F
University Pkwy & Town Center Pkwy	Signalized	22.0	C	53.6	D
Cooper Creek Blvd & Tourist Center Dr	Unsignalized	6.6	A	59.4	F
Cattlemen Rd & University Town Center Dr	Signalized	13.5	B	46.3	D

12.1.7 SR 780 (Fruitville Road)

A summary of overall intersection delay and LOS for the existing AM and PM peak hour conditions is provided in **Table 12-7** for Fruitville Road. As shown below, all study area intersections are operating at LOS D or better except for the Cattlemen Road intersection, which is operating at LOS E in the AM peak hour and LOS F in the PM peak hour. Queuing for the eastbound through movement at Cattlemen Road in the PM peak hour is more than 1 mile long due to traffic (approximately 2,600 vehicles) stacking in the right lane to access both the southbound and northbound (loop) on-ramps. At the I-75 ramp terminal intersections, the northbound off-ramp left-turn movement is operating at LOS E in both the AM and PM peak hours and the southbound off-ramp left- and right-turn movements are operating at LOS E in the PM peak hour. The eastbound through movement at the I-75 southbound ramp terminal also has a queue of approximately 1,300 feet in both peak hours that spills back beyond the Cattlemen Road intersection, but overall operations are LOS D or better.

Table 12-7 SR 780 (Fruitville Road) Peak Hour Vissim Analysis Summary

Intersection	Traffic Control	AM Peak		PM Peak	
		Delay (sec/veh)	Estimated LOS	Delay (sec/veh)	Estimated LOS
Fruitville Rd & Cattlemen Rd	Signalized	70.1	E	93.4	F
Fruitville Rd & I-75 SB Ramps	Signalized	40.5	D	30.5	C
Fruitville Rd & I-75 NB Ramps	Signalized	27.5	C	21.2	C
Fruitville Rd & Coburn Rd W	Unsignalized	29.0	D	28.2	D
Fruitville Rd & Coburn Rd E	Signalized	34.6	C	30.3	C

12.1.8 SR 758 (Bee Ridge Road)

A summary of overall intersection delay and LOS for the existing AM and PM peak hour conditions is provided in **Table 12-8** for Bee Ridge Road. As shown below, the I-75 ramp terminal intersections are operating at LOS E in the AM peak hour. Multiple movements are operating at LOS F at both terminals, including the southbound right-turn, northbound left-turn, westbound left-turn, and westbound through movements. There is congestion at the Cattlemen Road intersection, which is operating at LOS E in both peak periods, that causes queue spill back that impacts the interchange. During the AM peak hour, queuing on the northbound off-ramp spills back to the I-75 mainline and the southbound off-ramp exceeds the available storage (see Section 12.3). Queuing for the eastbound through movement at Cattlemen Road in the PM peak hour exceeds the length of the network, which is 3,000 feet west of Maxfield Drive, due to traffic (approximately 1,700 vehicles) stacking in the right lane to access both the southbound and northbound (loop) on-ramps.

Table 12-8 SR 758 (Bee Ridge Road) Peak Hour Vissim Analysis Summary

Intersection	Traffic Control	AM Peak		PM Peak	
		Delay (sec/veh)	Estimated LOS	Delay (sec/veh)	Estimated LOS
Bee Ridge Rd & Maxfield Dr	Signalized	27.2	C	71.1	E
Bee Ridge Rd & Cattlemen Rd	Signalized	64.7	E	60.5	E
Bee Ridge Rd & I-75 SB Ramps	Signalized	72.9	E	48.0	D
Bee Ridge Rd & I-75 NB Ramps	Signalized	56.6	E	30.1	C
Bee Ridge Rd & Mauna Loa Blvd	Signalized	56.5	E	27.3	C
Cattlemen Rd & Maxfield Dr	Signalized	23.4	C	27.7	C

12.1.9 SR 72 (Clark Road)

A summary of overall intersection delay and LOS for the existing AM and PM peak hour conditions is provided in **Table 12-9** for Clark Road. As shown below, all study area intersections are operating at LOS D or better except for the I-75 northbound ramp terminal in the AM peak hour (LOS E, but near the LOS F threshold) and the Gantt Road intersection in the PM peak hour (LOS E). Multiple movements at the adjacent signalized intersections are operating at LOS F, including the eastbound through movement at Gantt Road in the PM peak hour. Queuing for the eastbound through movement in the PM peak hour exceeds 3,000 feet west of Gantt Road due to congestion and queuing at the

interchange, which causes queue spillback through the adjacent signalized intersections (Catamaran Drive and Gantt Road). The northbound left-turn movement at the I-75 northbound ramp terminal is operating at LOS F in the AM peak hour, with queuing that extends to the I-75 mainline. This movement is a single left-turn lane serving approximately 900 vehicles during the peak hour. The southbound left-turn movement at the I-75 southbound ramp terminal is also operating at LOS F in the PM peak hour, with queuing of approximately 900feet that exceeds the available storage (see Section 12.3).

Table 12-9 SR 72 (Clark Road) Peak Hour Vissim Analysis Summary

Intersection	Traffic Control	AM Peak		PM Peak	
		Delay (sec/veh)	Estimated LOS	Delay (sec/veh)	Estimated LOS
Clark Rd & Gantt Rd	Signalized	42.3	D	66.1	E
Clark Rd & Catamaran Dr	Signalized	12.4	B	16.7	B
Clark Rd & I-75 SB Ramps	Signalized	17.0	B	17.4	B
Clark Rd & I-75 NB Ramps	Signalized	79.3	E	40.4	D
Clark Rd & Queensbury Blvd	Unsignalized	27.2	D	22.4	C
Clark Rd & Hummingbird Ave	Unsignalized	24.4	C	19.1	C

12.1.10 SR 681

A summary of overall intersection delay and LOS for the existing AM and PM peak hour conditions is provided in **Table 12-10** for SR 681. As shown below, the Honore Avenue intersection is operating at LOS C in both the AM and PM peak hours. Queuing on SR 681 is minimal and has no impact on the I-75 mainline. The Honore Avenue intersection was primarily included in the Vissim models to platoon traffic more accurately onto northbound I-75.

Table 12-10 SR 681 Peak Hour Vissim Analysis Summary

Intersection	Traffic Control	AM Peak		PM Peak	
		Delay (sec/veh)	Estimated LOS	Delay (sec/veh)	Estimated LOS
SR 681 & Honore Ave	Signalized	24.8	C	26.8	C

12.1.11 Laurel Road

A summary of overall intersection delay and LOS for the existing AM and PM peak hour conditions is provided in **Table 12-11** for Laurel Road. As shown below, all study area intersections are operating at LOS C or better except for the unsignalized intersection at Discovery Way, which is operating at LOS E in the AM peak hour and LOS F in the PM peak hour. Although operating at LOS F, the delay for the southbound stop-controlled right-turn movement is less than 60 seconds in both peak hours. No other delay or queuing issues were observed at the interchange.

Table 12-11 Laurel Road Peak Hour Vissim Analysis Summary

Intersection	Traffic Control	AM Peak		PM Peak	
		Delay (sec/veh)	Estimated LOS	Delay (sec/veh)	Estimated LOS
Laurel Rd & Twin Laurel Blvd	Unsignalized	15.9	C	22.4	C
Laurel Rd & Pinebrook Rd	Signalized	24.5	C	25.7	C
Laurel Rd & I-75 SB Ramps	Signalized	15.9	B	25.2	C
Laurel Rd & I-75 NB Ramps	Signalized	18.8	B	17.9	B
Laurel Rd & Discovery Way	Unsignalized	47.9	E	55.1	F
Laurel Rd & Haul Rd	Signalized	26.1	C	23.8	C

12.1.12 Jacaranda Boulevard

A summary of overall intersection delay and LOS for the existing AM and PM peak hour conditions is provided in **Table 12-12** for Jacaranda Boulevard. As shown below, all study area intersections are operating at LOS C or better except for the I-75 northbound off-ramp in the AM peak hour, which is operating at LOS F. The I-75 northbound ramp terminal is unsignalized and the intersection LOS is based on the worst stop-controlled movement, which is the off-ramp left-turn movement. The off-ramp left-turn movement experiences delays of up to 3 minutes and queuing of over 2,400 feet. The off-ramp queue is approximately 100 feet from the I-75 mainline gore.

Table 12-12 Jacaranda Boulevard Peak Hour Vissim Analysis Summary

Intersection	Traffic Control	AM Peak		PM Peak	
		Delay (sec/veh)	Estimated LOS	Delay (sec/veh)	Estimated LOS
Jacaranda & Commerce Dr	Unsignalized	14.7	B	22.7	C
Jacaranda Blvd & I-75 NB Ramps	Unsignalized	175.6	F	11.9	B
Jacaranda Blvd & I-75 SB Ramps	Signalized	12.3	B	14.5	B
Jacaranda Blvd & Executive Dr	Signalized	24.7	C	28.1	C
Jacaranda Blvd & Oak Heritage Dr	Unsignalized	16.0	C	15.4	C

12.1.13 N River Road

A summary of overall intersection delay and LOS for the existing AM and PM peak hour conditions is provided in **Table 12-13** for N River Road. As shown below, all study area intersections are operating at LOS D or better, with the I-75 ramp terminal intersections operating at LOS C or better in the AM and PM peak hours. It should be noted that the I-75 southbound off-ramp right-turn movement in the PM peak hour is over 800 vehicles in a single lane, which exceeds the typical capacity for a stop-controlled movement. During calibration of the N River Road interchange, the off-ramp right-turn movement was modeled as a yield-controlled movement to hit GEH targets when comparing to field measured volumes. If stop-controlled behavior were adhered to, this off-ramp movement would experience significant delays and queuing that would impact southbound I-75.

Table 12-13 N River Road Peak Hour Vissim Analysis Summary

Intersection	Traffic Control	AM Peak		PM Peak	
		Delay (sec/veh)	Estimated LOS	Delay (sec/veh)	Estimated LOS
N River Rd & I-75 NB Ramps	Unsignalized	17.7	C	10.4	B
N River Rd & I-75 SB Ramps	Unsignalized	7.3	A	13.6	B
N River Rd & Subdivision Entrance	Unsignalized	6.6	A	32.7	D
N River Rd & Venice Ave	Signalized	30.9	C	46.5	D

12.2 Intersection Analysis Summary

Overall, the existing conditions analysis indicates that the I-75 ramp terminal intersections and adjacent signalized intersections are operating at LOS D or better in the AM and PM peak hours except for the following locations:

- Moccasin Wallow Road and I-75 Northbound Ramp Terminal: LOS E in AM peak hour (unsignalized).
- US 41 and I-275 Southbound Ramp Terminal: LOS E in AM Peak hour and LOS F in PM peak hour (unsignalized).
- University Parkway and Cattlemen Road: LOS E in PM peak hour.
- University Parkway and Market Street: LOS E in PM peak hour.
- Fruitville Road and Cattlemen Road: LOS E in AM peak hour, LOS F in PM peak hour.
- Bee Ridge Road and Cattlemen Road: LOS E in AM and PM peak hours.
- Bee Ridge Road and I-75 Southbound Ramp Terminal: LOS E in AM peak hour.
- Bee Ridge Road and I-75 Northbound Ramp Terminal: LOS E in AM peak hour.
- Bee Ridge Road and Mauna Loa Boulevard: LOS E in AM peak hour.
- Clark Road and I-75 Northbound Ramp Terminal: LOS E in AM peak hour.
- Jacaranda Boulevard and I-75 Northbound Ramp Terminal: LOS F in AM peak hour.

Multiple unsignalized intersections or driveways are operating at LOS E or F, but the side street/driveway delays do not impact interchange operations. Individual movements at the interchange ramp terminal intersections that are operating at LOS E or F in the AM or PM peak hours are summarized below:

- Moccasin Wallow Road: I-75 northbound off-ramp left-turn movement (unsignalized) is operating at LOS E in the AM peak hour.
- US 41: I-275 southbound off-ramp left-turn movement (unsignalized) is operating at LOS E and F in the AM and PM peaks, respectively.
- US 301: I-75 northbound and southbound off-ramp left-turn movements are operating at LOS E in the AM and PM peak hours. The eastbound left-turn movements to northbound and southbound I-75 are also operating at LOS E or F in both the AM and PM peak hours.

- SR 64: Eastbound left-turn movement to northbound to I-75 northbound is operating at LOS E in the AM and PM peak hours.
- SR 70: I-75 northbound and southbound off-ramp left-turn movements are operating at LOS E in the AM and PM peak hours. The eastbound left-turn movement to I-75 northbound is operating at LOS F in the AM peak hour and LOS E in the PM peak hour.
- University Parkway: I-75 southbound right-turn and I-75 northbound left-turn movements are operating at LOS E in the AM peak hour. The eastbound through movement at the I-75 southbound ramp terminal intersection is operating at LOS E in the AM peak hour and the westbound through movement at the I-75 northbound ramp terminal intersection is operating at LOS E in the PM peak hour.
- Fruitville Road: I-75 northbound off-ramp left-turn movement is operating at LOS E in the AM and PM peak hours and the I-75 southbound off-ramp right-turn movement is operating at LOS E in the PM peak hour.
- Bee Ridge Road: I-75 southbound left- and right-turn movements and I-75 northbound off-ramp left-turn movement are operating at LOS E or F in the AM and PM peak hours. At the I-75 southbound ramp terminal intersection, the eastbound through and westbound through movements are operating at LOS E in the AM peak hour and the westbound left-turn movement is operating at LOS F in both the AM and PM peak hours. At the I-75 northbound ramp terminal intersection, the westbound through movement is operating at LOS F and E in the AM and PM peak hours, respectively.
- Clark Road: I-75 northbound and southbound off-ramp left-turn movements are operating at LOS E or F in the AM and PM peak hours. The westbound through movement at the I-75 northbound ramp terminal intersection is operating at LOS F and LOS E in the AM and PM peak hours, respectively. The westbound left-turn movement at the I-75 southbound ramp terminal intersection is operating at LOS E in the PM peak hour.
- Jacaranda Boulevard: I-75 northbound off-ramp left- and right-turn movements (unsignalized) are operating at LOS F in the AM peak hour.

Queuing at the interchange ramp terminals that spills back to adjacent intersections, or queuing at adjacent intersections that impacts the I-75 interchanges are summarized below:

- University Parkway: Queuing in the eastbound direction at Market Street (predominately from the eastbound left-turn movement) spills back to the I-75 northbound ramp terminal during the AM peak hour, resulting in over 1,600 feet of queuing on the off-ramp that exceeds the available storage. During the PM peak hour, queuing in the westbound direction at Market Street spills back to Town Center Parkway. Although this queuing does not impact interchange operations, it limits the amount of traffic that is able to reach I-75 during peak periods.
- Fruitville Road: Queuing for the eastbound through movement at Cattlemen Road in the PM peak hour is more than 1 mile long due to traffic (approximately 2,600 vehicles) stacking in the right lane to access both the southbound and northbound (loop) on-ramps. The eastbound through movement at the I-75 southbound ramp terminal also has a queue of approximately 1,300 feet in both peak hours that spills back beyond the Cattlemen Road intersection.

- Bee Ridge Road: The adjacent Cattlemen Road intersection causes queue spill back, particularly during the AM peak period, that impacts the interchange and causes ramp queues to extend onto the I-75 mainline. Queuing for the eastbound through movement at Cattlemen Road in the PM peak hour exceeds the length of the network, which is 3,000 feet west of Maxfield Drive, due to traffic (approximately 1,700 vehicles) stacking in the right lane to access both the southbound and northbound (loop) on-ramps.
- Clark Road: Queuing for the eastbound through movement in the PM peak hour exceeds 3,000 feet west of Gantt Road due to congestion and queuing at the interchange, which causes queue spillback through the adjacent signalized intersections (Catamaran Drive and Gantt Road).

12.3 Ramp Queue Analysis

A summary of the AM and PM peak hour queue lengths for the I-75 interchange off-ramps is provided in **Table 12-14**. The storage lengths for the off-ramps were measured from the stop bar to the end of the turn lanes, including taper, and were compared to the maximum queue lengths recorded in Vissim. The ramp length from the stop bar to the I-75 gore point has also been provided for reference. As shown below, there are ten off-ramps that exceed the available turn lane storage during the AM or PM peak hours. Two of these ramps have maximum queue lengths that exceed the length of the ramp in the AM peak hour, including the Bee Ridge Road northbound off-ramp and the Clark Road northbound off-ramp. Queuing at the Bee Ridge Road interchange results in minor slowdowns in the right-most lane of I-75. It should be noted that the Bee Ridge Road southbound off-ramp queue length exceeds the length of the ramp during the third hour of the AM peak period, resulting in moderate congestion north of the interchange. The Clark Road off-ramp queuing causes more significant breakdown in the right-most lane and minor slowdowns in the middle lane of I-75.

Table 12-14 Vissim Ramp Queue Analysis Summary

Interchange	Ramp	Storage (ft)	Ramp Length (ft)	AM Peak	PM Peak	Exceeds Storage?	Exceeds Ramp?
				Max Queue (ft)	Max Queue (ft)		
Moccasin Wallow Road	I-75 NB Off-Ramp	375	2280	119	80	No	No

	I-75 SB Off-Ramp	1220	1725	249	628	No	No

12.4 Arterial Analysis

A summary of the AM and PM peak hour average speeds on the interchange arterials is provided in **Table 12-15** and **Table 12-16**. The average speed was calculated based on the same travel time segments used for calibration. Average speeds ranged from 12 to 43 mph in both the AM and PM peak hours and will be used for comparison with future conditions. Notable arterials with reduced operating speeds during peak periods include both directions of University Parkway, Fruitville Road, and Bee Ridge Road, and westbound Clark Road. Although not directly comparable to free flow speed due to the presence of signals along the corridor, the average speeds at these locations are 20 to 30 mph below the posted speed limit of 45 mph.

Table 12-15 Interchange Arterial Vissim Analysis Summary – AM Peak Hour

Interchange	Dir	Segment	Travel Time (min)	Length (miles)	Average Speed (mph)

12.5 I-75 Mainline Analysis

An operational analysis of the existing conditions on the I-75 mainline was performed using the calibrated combined Vissim model. While a peak period analysis was performed using one shoulder hour each before and after the peak hour, the travel time and LOS results discussed in the following subsections are for the peak hour only. The analysis results discussed below are based on the average of ten simulation runs. In Vissim, the mainline LOS is computed from a microsimulation analysis and is therefore reported as an “estimated LOS.” Vissim quantifies speed and density more realistically than typical equation-based HCM methods because it tracks individual vehicle movements and interactions. The estimated LOS for existing conditions is based on HCM criteria and thresholds for basic freeway, merge, diverge, and weaving segments.

12.5.1 I-75 Mainline Travel Times

A summary of the AM and PM peak hour travel times on northbound and southbound I-75 is provided in **Table 12-17** and **Table 12-18**. The results will be used for comparison with future conditions and include travel times along the entire corridor as well as shorter segments covering multiple interchanges. The average speed from south of River Road to north of Moccasin Wallow Road was 71 mph in both directions of I-75 during the AM peak hour. During the PM peak hour, the average speed along the corridor was 70 mph in both directions of I-75.

Table 12-17 I-75 Mainline Travel Time – AM Peak Hour

Segment	Travel Time (min)	Length (miles)	Average Speed (mph)
I-75 Northbound - South of River Rd to North of Moccasin Wallow Rd	34.3	40.6	71
I-75 Northbound - South of Riveer Rd to SR 681	8.2	9.7	71
I-75 Northbound - SR 681 to Bee Ridge Rd	6.9	7.5	66
I-75 Northbound - Bee Ridge Rd to SR 70	8.4	9.9	71
I-75 Northbound - SR 70 to US 301	6.1	7.3	72
I-75 Northbound - US 301 to North of Moccasin Wallow Rd	5.0	6.2	74
I-75 Southbound - North of Moccasin Wallow Rd to South of River Rd	34.5	40.6	71
I-75 Southbound - North of Moccasin Wallow Rd to US 301	5.0	6.2	73
I-75 Southbound - US 301 to SR 70	6.3	7.3	70
I-75 Southbound - SR 70 to Bee Ridge Rd	9.0	9.9	66
I-75 Southbound - Bee Ridge Rd to SR 681	6.4	7.6	71
I-75 Southbound - SR 681 to South of River Rd	8.0	9.7	72

Table 12-18 I-75 Mainline Travel Time – AM Peak Hour

Segment	Travel Time (min)	Length (miles)	Average Speed (mph)
I-75 Northbound - South of River Rd to North of Moccasin Wallow Rd	34.8	40.6	70
I-75 Northbound - South of Riveer Rd to SR 681	7.9	9.7	74
I-75 Northbound - SR 681 to Bee Ridge Rd	6.3	7.5	72

I-75 Southbound - SR 681 to South of River Rd	8.3	9.7	70

12.5.2 I-75 Mainline Speeds

A summary of the average speeds along northbound and southbound I-75 is provided in **Figure 12-1** and **Figure 12-2** for the AM peak period and **Figure 12-3** and **Figure 12-4** for the PM peak period. As shown below, the average speeds along I-75 from south of River Road to north of Moccasin Wallow Road are at or near free flow (greater than 65 mph) for most of the corridor, with some areas experiencing minor slowdowns between 55 and 65 mph, particularly at or near interchanges. The following locations experience minor to more significant congestion along I-75:

- I-75 northbound experiences minor congestion (speeds between 45 and 55 mph) around the Fruitville Road interchange during both the AM and PM peak periods. Similar congestion occurs around the SR 70 and US 301 interchanges in the PM peak period. The low speed, loop ramp exit to US 301 is a contributing factor to the queuing and congestion on I-75 at that location.
- I-75 northbound experiences moderate congestion (speeds between 35 and 45 mph) at the off-ramp to Bee Ridge Road during the AM peak period due to queuing that spills back onto the I-75 mainline.
- I-75 northbound experiences more significant congestion (speeds between 25 and 35 mph) at the off-ramp to the Clark Road interchange during the AM peak period due to queuing that spills back onto the I-75 mainline.
- I-75 southbound experiences minor congestion (speeds between 45 and 55 mph) between the SR 70 and University Parkway interchanges for a brief period during the AM peak period.
- I-75 southbound experiences minor congestion (speeds between 45 and 55 mph) between the University Parkway and Fruitville Road interchanges during the AM peak period due to the high volume of off-ramp peak hour traffic (approximately 2,200 vph) at Fruitville Road.

Although the southbound off-ramp queuing does not spillback onto the I-75 mainline, the ramp is operating over-capacity, resulting in significant slowdowns in the right-most lane of I-75 that extend to the University Parkway on-ramp. The average speed across all lanes is 45 to 55 mph, but the right-most lane experiences speeds below 35 mph.

- I-75 southbound experiences moderate congestion (speeds between 35 and 45 mph) between Bee Ridge Road and Fruitville Road in the AM peak period due to off-ramp queuing at Bee Ridge Road that spills back onto the I-75 mainline. Queuing approaches the end of the ramp during the peak hour, causing minor congestion, but eventually extends onto I-75 resulting in more significant slowdowns.

Figure 12-1 I-75 Northbound Speeds – AM Peak Period

Figure 12-2 I-75 Southbound Speeds – AM Peak Period

Figure 12-3 I-75 Northbound Speeds – PM Peak Period

Figure 12-4 I-75 Southbound Speeds - PM Peak Period

12.5.3 I-75 Mainline Operations

A summary of mainline operations (density, speed, LOS and volume served) is provided on **Figure 12-5** through **Figure 12-7** for the existing AM peak hour and **Figure 12-8** through **Figure 12-10** for the existing PM peak hour. The Vissim analysis results for each link segment are based on the weighted average per lane and an approximate 1,500-foot influence area for merge and diverge segments as defined in the HCM. As shown below, I-75 southbound is operating at speeds between 56 and 76 mph in the AM peak hour and between 59 and 76 mph in the PM peak hour. I-75 northbound is operating at speeds between 49 and 78 mph in both the AM and PM peak hours. More than 93 percent of the traffic demand is being served in both peak hours.

Excluding impacts caused by existing construction, the corridor is operating at an estimated LOS of D or better in both peak hours. During the AM peak hour, the LOS D operations are localized to the I-75 northbound diverges at Clark Road and Fruitville Road. It should be noted that the I-75 northbound diverge to Clark Road is operating at LOS F at the end of the AM peak period due to off-ramp queuing that spills back onto the I-75 mainline. Additionally, I-75 southbound between Fruitville Road and Bee Ridge Road is operating at LOS D at the end of the AM peak period, compared to LOS C during the peak hour, due to queuing on the Bee Ridge Road off-ramp that eventually spills back onto the I-75 mainline. During the PM peak hour, the LOS D operations are localized to I-75 northbound at the Fruitville Road on-ramps, I-75 northbound between University Parkway and SR 70, I-75 northbound north of SR 70, and I-75 northbound between SR 64 and US 301.

12.6 Network Performance Summary

The network performance results shown below in **Table 12-19**. provide a good assessment of overall operations within the study area and will be used for comparison with future conditions. Latent demand and latent delay apply to vehicles that cannot enter the network due to queuing and provide a good indication of capacity constraints within the model. There were approximately 80 unserved vehicles in the AM peak hour and 270 vehicles in the PM peak hour. The latent demand occurred primarily on driveways or high-volume side streets that intersect with high-volume arterials, such as Mauna Loa Boulevard at Bee Ridge Road. The latent demand represents just 0.1 and 0.4 percent of all active or arrived vehicles in the network in the AM and PM peak hours, respectively.

Table 12-19 Existing Conditions Vissim Network Performance Summary

Peak Period	Average Speed (mph)	Average Delay (sec)	Total Travel Time (hr)	Total Delay (hr)	Arrived Vehicles (veh)	Latent Demand (veh)	Latent Delay (hr)	Total Delay + Latent Delay (hr)

Traffic Methodology Statement

Traffic Methodology Statement

I-75 Express Lanes PD&E Study in Sarasota and Manatee Counties

The purpose of this Statement is to summarize the process that will be employed to produce existing (2019) and design year (2045) annual average daily traffic (AADT) and peak hour volumes at key intersections for each interchange area along I-75 in Sarasota and Manatee Counties.

A. Data Collection

- 1) Twenty-nine (29) 72-hour bi-directional (approach and departure volumes at 15-minute increments) machine classification counts, one hundred and one (101) 72-hour bi-directional (approach and departure volumes at 15-minute increments) machine volume counts, and seventy-five (75) 2-hour AM (from 7:00 AM to 9:00 AM) and PM (from 4:00 PM to 6:00 PM) turning movement, pedestrian, and bicycle counts were collected for the study area.
- 2) FDOT counts were collected as needed from Florida Traffic Online. These counts were used for the I-75 mainline in particular.

B. Traffic Factors

- 1) An axle adjustment factor (AF) and a seasonal factor (SF) will be applied to all machine counts as appropriate.
- 2) In accordance with the FDOT "Project Traffic Forecasting Handbook", as arterials, collectors, and limited access facilities in an urbanized area, the Standard K-factor of 9.0 percent is recommended.
- 3) The calculated D-factors from the turning movement counts/tube counts will be used as seed D-factors for the I-75 mainline and cross streets, while using the low to high D_{30} factors from the FDOT "Project Traffic Forecasting Handbook" as the minimum and maximum values.
- 4) The T-factor will be calculated based on the weighted averages from the 72-hour class counts for the I-75 mainline and cross streets for each interchange area.
- 5) The AM and PM peak hours will be computed for the entire subarea network using all collected tube counts. Localized peak hours will be calculated for each of the interchange areas.

C. Existing Year (2019) Design Traffic Volume Development

- 1) 72-hour tube counts will be reviewed for outlier days. That is, the AM and PM peak hour volumes for each day will be compared to the other two days for that count location. If one of the counts differs from the average of the two highest days by more than five (5) percent, then it is excluded. If multiple days meet this criterion then the outlier may be the higher value so each value is instead compared to the average of the two minimum days.
- 2) Significant imbalances between turning movement counts (TMCs) will be identified as potential sink/source locations. For these locations, a review of the aerial photos and maps will be conducted to determine if there is cause for adding a sink/source (e.g., a neighborhood connection, driveways) to the network. These sink/source locations will not necessarily represent an individual driveway, but may represent multiple driveways (similar to a centroid connector in a regional travel demand model). The calculated imbalance between observed count data will be used to understand if the source/sink is an overall producer or attractor during

a given period. A review of land use and engineering judgement will be used to compute the quantity of trips. Both the “*FDOT Project Traffic Forecasting Handbook*” and the “*Transportation Research Board (TRB) National Cooperative Highway Research Program (NCHRP) Report 765 – Analytical Travel Forecasting Approaches for Project-Level Planning and Design*” will be reviewed for methodological consistency.

- 3) An initial balancing of volumes during the system-wide peak hours on I-75 will be done using the FDOT counts at the northern and southern ends of the study area on the mainline and the tube counts collected on each ramp. The FDOT counts will be adjusted to ensure balancing. AADT will be reviewed on I-75 for quality after balancing by comparing the newly balanced volumes with the FDOT counts.
- 4) An existing network will be constructed in PTV VISUM by importing an extracted subarea from the base year of the sub-area validated District 1 Regional Planning Model (D1RPM). Speeds and capacities from the D1RPM will be used directly as available.
- 5) Additional driveways will be added to the D1RPM derived VISUM network where counts have been collected but the driveway does not exist in the model.
- 6) Zones will be created at all external locations on the network in VISUM. These zones will serve as the origins and destination points for the subarea. The number of AM and PM peak hour production and attraction trips at each of these zones will be computed directly from observed tube counts. If a tube count is not available at one of these zones, the appropriate approach from the turning movement count will be used instead. For those zones identified previously as a sink/source, the productions and attractions computed for that location will be used.
- 7) The productions and attractions for these zones that have been computed will then be balanced. Since the study area is a closed system, all trips entering the system must also leave the system. This same logic also applies to each interchange in the study area. By balancing the productions and attractions at each interchange and then balancing them together as a system (always upwards), no trips will be lost. This will result in a balanced set of production and attractions.
- 8) Balancing of the existing volumes will be completed using the TFLOW Fuzzy application in PTV VISUM. TFLOW Fuzzy is a matrix manipulation tool design to take an existing origin-destination matrix and adjust it so that the resulting assignment of that matrix matches the input attributes - turning movement, link, and zone counts. An overview of this process is provided in **Figure 1** below. In addition to a balanced set of turning movement counts, this volume balancing process also results in an existing year origin-destination matrix for the study area validated to the collected traffic counts.

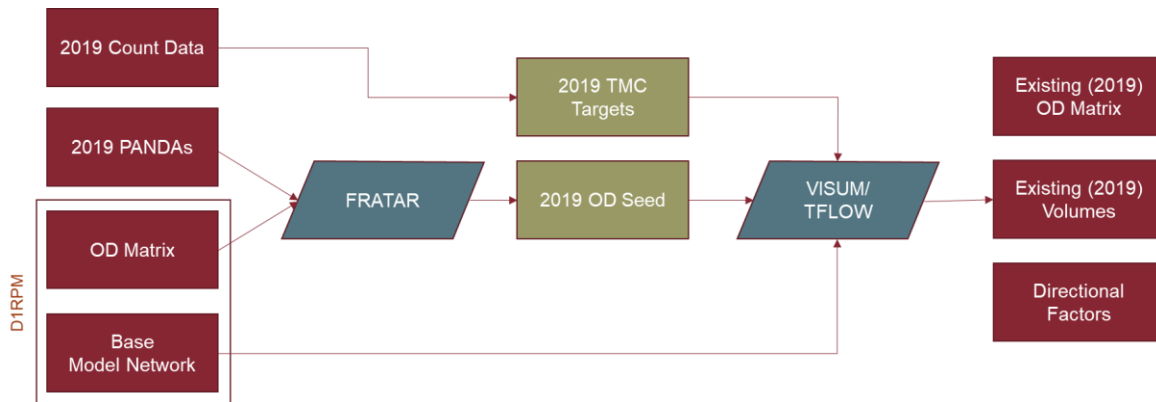

Figure 1: Existing Volumes Balancing Process

- 9) A seed origin-destination matrix will be created for each of the two peak hours (AM and PM). This seed origin-destination matrix will be produced using a sub-area origin-destination matrix extraction from the D1RPM base year to ensure that general travel patterns observed in the D1RPM will be replicated in the more detailed origin-destination matrix developed using TFLOW Fuzzy. To accomplish this, a lookup table between the zones in the subarea extraction and the VISUM network zones will be created. For places where the two models do not match (i.e., added driveways), either a nearby TAZ or roadway link will be substituted. This subarea extracted origin-destination matrix from the D1RPM will be matched to the counted origins and destinations at the external zones using iterative proportional fitting (IPF) methods outlined in NCHRP report 765 “Analytical Travel Forecasting Approaches for Project-Level Planning and Design”. These seed origin-destination matrices will be used as inputs to TFLOW Fuzzy.
- 10) Attribute files, used as inputs to TFLOW Fuzzy, will be developed for all turning movement counts, tube counts, and zone origins and destinations. These attribute files define systemwide AM and PM peak hour count values at these locations, which is then used by TFLOW Fuzzy to manipulate the seed origin-destination matrix to match the peak hour counts within defined tolerances.
- 11) An iterative process starting with the most “fuzzy” tolerance of volumes to counts and ending at a more narrow tolerance will be used to match the origin-destination matrix to the collected counts. A final consistency check on all turning movement counts and tube counts by direction will be done by ensuring that the difference between the processed volume and count does not exceed 10% and 35 trips. These metrics are based on our engineering judgement and would generally be in line with traditional volume balancing techniques. In addition to this movement level check, a systemwide check that the difference between all counts and VISUM processed turning movement volumes is less than 5 percent to meet the VISSIM calibration criteria provided in Table 7-7 of the “FDOT Traffic Analysis Handbook.”
- 12) In addition to validation of the count values for turning movement counts, relative flows at the TMCs will also be checked to confirm there are no significant changes that might point to changes in distribution patterns.
- 13) In addition to our individual count level threshold, a final QC check will be performed at each external zone in the VISUM model. AADT will be re-calculated from the maximum of the AM and PM peak hourly volumes at each study segment using a standard K factor and the count specific D factor. This modeled AADT will be compared to the counted AADT value. To measure these differences, percent root mean square error (RMSE) values defined in the FDOT “Project Traffic

Forecasting Handbook” will be used to define what tolerance is acceptable or preferred. **Equation 1** below defines the process for calculating percent RMSE and **Table 1** below provides the traffic assignment accuracy levels. This practice is in line with typical validation techniques for travel demand models in the State of Florida. Differences in AADT exceeding 10 percent on links, with an AADT greater than 1,000, will be reviewed to ensure the change in volume is appropriate based on engineering judgement.

- 14) Access and egress for I-75 is a key component of this study. As such, special care will be taken in validating ramp volumes.

Equation 1: Percent RMSE Calculation

$$\%RMSE = \frac{(\sum_j (Model_j - Count_j)^2 / (NumberofCounts - 1))^{0.5} * 100}{(\sum_j Count_j / NumberofCounts)}$$

D. No Build 2040 Traffic Forecasts

- 1) **Figure 2** below outlines the 2040 No-Build Forecasting Approach.

Figure 2: No-Build 2040 Forecasting Approach

- 2) The Department provided version of the District 1 Regional Planning Model (D1RPM), with the base year 2015, will be used to develop design traffic forecasts. Growth will be observed in the model outputs between the base year (2015) and horizon year (2040). This analysis, along with count site trends and socio-economic growth will form the basis for identifying future growth rates. Using direct model volumes will be preferred with model output correction factors (MOCF) from FDOT applied as necessary. In cases where there are unexpected variations in growth, variations will be documented and conveyed to the Department and IPM.
- 3) The no-build demand volumes will be based upon the D1RPM CF network, with I-75 (within the bounds of the D1RPM) coded as a 10-lane general use scenario, to establish unconstrained demand as the basis for analysis. This unconstrained scenario will ensure that latent demand is adequately captured.
- 4) Horizon year (2040) Model AADTs at network inputs will be collected and approved existing volume D-factors (for a given period) and standard K will be applied to develop a forecasted set of productions and attractions. This matrix will then be balanced (always up) to ensure no loss in the system.
- 5) The horizon year origin-destination matrix will be developed using a FRATAR process using the existing origin-destination matrix and the horizon year productions and attractions as the target.

The resulting horizon year origin-destination matrix will be assigned (using 20 iterations) to a year 2040 VISUM network which will be derived from the 2040 cost-feasible network included in the validated D1RPM using capacities and speeds from the model network as available. The resulting network will be reviewed for reasonableness and consistency.

- 1) **Figure 3** below outlines the 2045 No-Build Forecasting Approach.

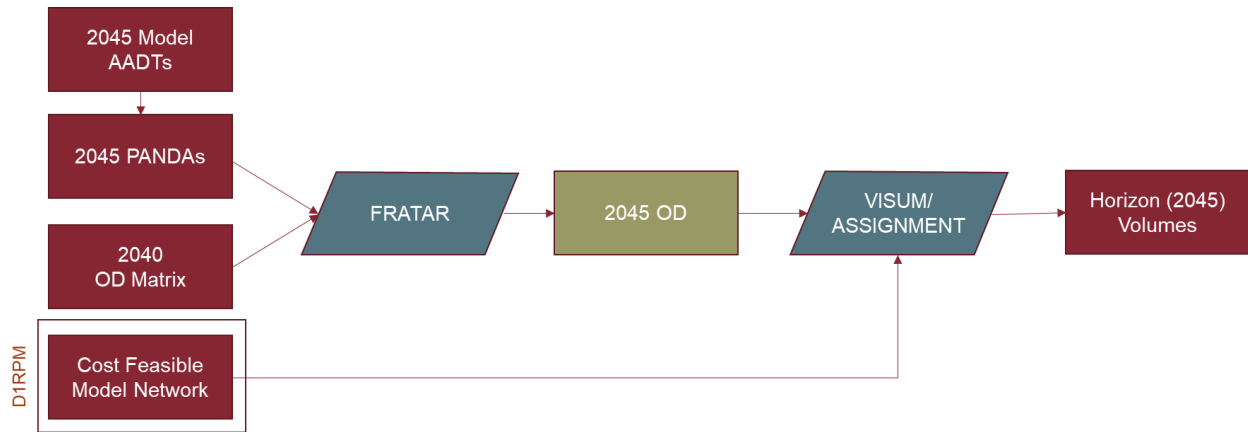

Figure 3: No-Build 2045 Forecast Procedure

- 2) Once it is agreed that the procedure is accurately portraying network assignment and is consistent with model forecasts, the 2019 and 2040 PANDAs will be linearly interpolated at each count site to develop 2045 PANDAs. These PANDAs will again be balanced (always up) and then will use the Fratar process to develop 2045 OD matrices utilizing the 2040 matrices as their seed.
- 3) The resultant 2045 OD matrices will then be assigned (20 iterations) to the network in VISUM utilizing user equilibrium assignment. The resulting network assignment will be reviewed for reasonableness and forecast consistency.
- 4) Input and turning movement volumes will be reviewed to ensure growth between the 2040 and 2045. Where negative growth is observed, route choice will be checked to note whether route diversion is the reason for distribution change or if additional action is required. D-Factors at network inputs will again be checked for reasonableness against Table 2-2 in the Project Traffic Forecasting Handbook (PTFH).

F. Build 2045 Traffic Forecasts

- 1) The D1RPM developed to support this effort will include three alternatives. The first alternative will be the 2040 cost-feasible network, the second alternative will be the 2040 cost-feasible network with one additional lane on I-75. The second alternative will be the 2040 cost-feasible network with two additional lanes on I-75.
- 2) Build alternative testing will consist of manipulating network coding and reassigning to the network via user equilibrium assignment as prescribed in the previous step.
- 3) Any changes in demand along corridors within the network will be documented and provided for Department review.
- 4) Any interim assignment needed will be developed by linearly interpolating between the 2019 and 2045 PANDAs, then applying the Fratar procedure with the 2045 OD matrices serving as the seed for development. Assignment will again be via user equilibrium assignment and developed traffic characteristics will be checked for forecast consistency and reasonableness as previously documented.

E. Documentation

- 1) At each of the following steps, quality control documentation will be provided to the Department for review. This documentation will include the quality checks referred to in this methodology and will be presented to the Department in a way that will facilitate review.
 - a. Existing Volume Development
 - b. 2045 'No-Build' Volume Development
 - c. 2045 'Ultimate' Build Volume Development
- 2) All volume development and traffic forecasts outlined above will be documented in a Project Traffic Development Memorandum. The following scenarios will be developed for this effort:
 - a. Existing (2019)
 - b. No Build (2045)
 - c. Build 'Ultimate' (2045)

Appendix B

Safety Methodology Statement

I-75 NORTH CORRIDOR MASTER PLAN

EXISTING CONDITIONS TRAFFIC TECHNICAL MEMORANDUM

Safety Methodology Statement

I-75 Express Lanes PD&E Study in Sarasota and Manatee Counties

The purpose of this Statement is to summarize the process that will be employed to collect crash data and determine areas with a high crash frequency for the existing corridor along I-75 south of N River Road to north of Moccasin Wallow Road. Additionally, future predicted crash rates will be determined based on proposed improvements along the corridor. The methodology will be based on the predictive method for freeways, which is included in the 2014 supplement to the 1st Edition of the *Highway Safety Manual* (HSM). The predictive method will allow for a safety comparison between alternatives based on proposed design elements, operational treatments, and future growth on the facility.

A. Crash Data Collection

- 1) Crash data will be collected from the Florida Department of Transportation (FDOT) Crash Analysis Reporting System (CARS) along mainline I-75 and state facilities and from the University of Florida's Signal Four Analytics for non-state roads for the 5 most recent years. Crash data will be obtained for the I-75 mainline from south of N River Road to north of Moccasin Wallow Road and for each of the following cross streets:
 - N River Road
 - Jacaranda Boulevard
 - Laurel Road
 - SR 681
 - SR 72 Clark Road
 - SR 758 Bee Ridge Road
 - SR 780 Fruitville Road
 - CR 610 University Parkway
 - SR 70
 - SR 64
 - US 301 (Ellenton)
 - I-275 at US 41
 - I-275
 - Moccasin Wallow Road

- 2) The crash data will be divided into analysis areas as found in **Figure 1** and will fall into one of the following location types:
 - Intersections
 - Arterial Facilities
 - Merge/Diverge Influence Areas
 - Ramp Areas
 - Limited Access Facilities

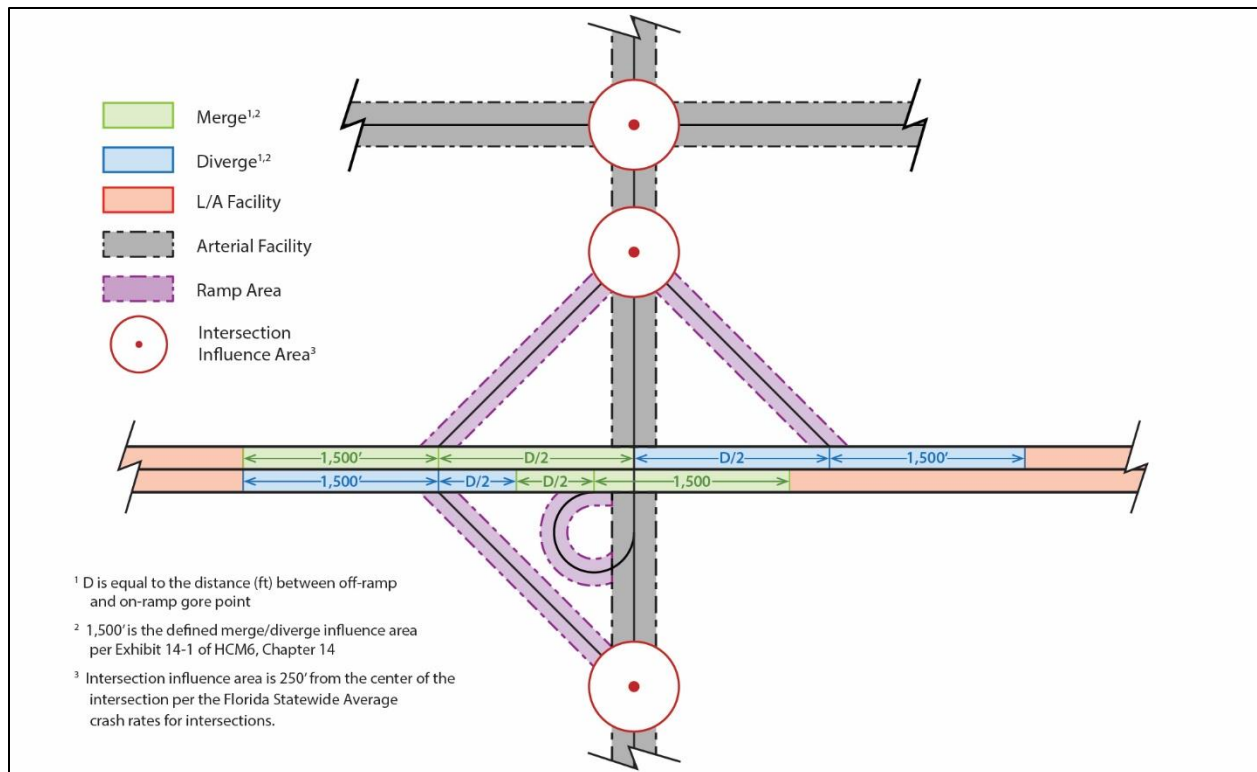

Figure 1: Crash Analysis Areas

B. Crash Characteristics

- 1) Crash data for each location will be divided by crash type. Crash types may consist of, but are not limited to, any of the following: angle, rear-end, sideswipe, head-on, hit fixed object, pedestrian, and bicycle related crashes.
- 2) Crash data for each location will be divided by weather condition. Weather conditions may consist of, but are not limited to, any of the following: clear, rain, and cloudy.
- 3) Crash data for each location will be divided by lighting condition. Lighting conditions may consist of, but are not limited to, any of the following: daylight, dark-lighted, dark-not lighted, dawn, and dusk.
- 4) Crash data for each location will be divided by injury severity, as defined by the FDOT KABCO crash costs from the FDOT Design Manual. Injury severities consist of the following: property damage only, minor injury, moderate injury, severe injury, and fatality. Using the KABCO crash costs, the economic loss to society for each crash severity type will be determined from the crash data. Crash severity for the analysis period as a whole will be summarized in tabular format by time of day, and crash severity trends over time will be summarized as a graph. Locations where pedestrian related, bicycle related, and/or fatal crashes occurred will be further analyzed for potential causes and/or patterns. This analysis will include a more thorough written description of the long-form crash report.

- 5) Crash data for each interchange will be summarized by three heat maps to show locations of relatively high and low crash frequency within the interchange (one for northbound I-75, one for southbound I-75, and one for the surface street intersections with the I-75 ramps). Crashes involving bicycles, pedestrians, severe injuries, or fatalities will be diagrammed individually to show their general location.

C. Crash Ratios

- 1) Crash rates will be calculated for each location using the following formula¹:

$$\text{Crash Rate} = \frac{1,000,000 * [5 \text{ Year Total Crashes}]}{365 * [\text{Number of Years}] * [5 \text{ Year Average AADT}] * \text{Segment Length (mi)}}$$

The resulting crash rate will be divided by the state and districtwide average for each location based on its facility and area type to determine the state and districtwide crash ratios.

- 2) A state or districtwide crash ratio of greater than 1.0 indicates the location has a greater crash frequency than the statewide average. Locations with a crash ratio of greater than 1.0 will be further analyzed to determine if an underlying crash cause is present.

D. Predictive Crash Analysis

If required by the January 2018 Interchange Access Request Users Guide, predictive crash analysis will be performed as described below.

- 1) All relevant geometric data on segments and ramps will be identified as inputs to the predictive method (e.g., number of through lanes, lane width, shoulder widths, clear zones, etc.)
- 2) Crash data collected and summarized in Parts B and C above will be assigned to the appropriate segment or ramps per criteria outlined in Section B.2.3 of Appendix B of the HSM.
- 3) AADTs collected and summarized in Parts B and C above will be assigned to each segment and ramp.
- 4) The appropriate safety performance functions (SPF), from Chapters 18 and 19 of the 2014 supplement to the latest HSM will be identified for each freeway segment and interchange.
- 5) Appropriate crash modification factors (CMF) will be identified for each segment and interchange. These CMFs will come from Chapters 18 and 19 of the 2014 supplement to the latest HSM if available, or from the FHWA Crash Modification Factor Clearinghouse if not.
- 6) Calibration factors for SPF's found in Chapters 18/19 of the HSM (freeways and interchanges) are not listed on FDOT's Safety Website. The latest calibration factors are dated 2012, prior to the release of the 2014 supplement to the HSM which contained Chapters 18 and 19. A cursory review of recent PD&E studies has not indicated whether or not the predictive method has been used on freeways or interchanges in the State and it is unclear if calibration factors have been developed in the past five years. The HSM indicates that 30 to 50 sites are necessary to develop a calibration

¹ Based on the FHWA crash rate calculation formula. However, FDOT calculates its crash rates in terms of million vehicle miles traveled (VMT) for segments rather than 100,000,000 VMT, so 1,000,000 is used as a constant for both equations.

factor. For freeways, this would be 0.1 to 1.0 mile lengths. Crash data, volumes, and other data needed to use the predictive method must be available for the past three years for each site type. For each site type, a minimum of 300 fatal or injury crashes must be included and additional sites must be included until that minimum number is reached. Each site type corresponding to a SPF will need to be evaluated separately by number of lanes and area type.

- 7) Appendix B of the HSM will be used to identify which sites and segments the Empirical Bayes (EB) method is appropriate. Section B.2 of Appendix B indicates that the EB method is not appropriate for new alignment along a portion of the project length; however, the EB method may be applied at sites where it is appropriate (i.e., the EB method does not need to be applied in an all-or-nothing fashion).
- 8) If required by the January 2018 Interchange Access Request Users Guide, the EB Method, outlined in Sections B.2.4 and B.2.6 of Appendix B of the HSM 2014 Supplement will be used as appropriate to leverage the combination of observed crash frequency (using historical data) and predicted crash frequency (using an SPF) to determine a more reliable expected average crash frequency that accounts for both the variability in sites used to develop an SPF and the inherent variability in observed crash data. The resulting expected average crash frequency will be used in further safety analysis in the same fashion that observed crash frequency would be used, and also to predict crash frequency in future years as appropriate.
- 9) Fatal/injury crash rates and property-damage only crash rates will be calculated, as described above for each scenario.
- 10) Crash Severity Distribution Functions (SDF) will be used to further quantify the crash frequency by the KABCO crash types defined in Section B.4 above.

The following table from the January 2018 Interchange Access Request Users Guide describes the instances in which we would utilize the EB Method, SPFs, and/or CMFs:

Table 3-1: Safety Analysis Types

IJR	Calculation of Crash Rates	Crash Diagrams	Description of Existing Crash Trends	Safety Performance Functions	→	Crash Reduction Estimation (CMF's)	Benefit Cost Analysis (Optional)	Documentation
IMR	Calculation of Crash Rates	Crash Diagrams	Description of Existing Crash Trends	Safety Performance Functions	Empirical Bayes Method	Crash Reduction Estimation (CMF's)	Benefit Cost Analysis	Documentation
IOAR	Calculation of Crash Rates	Crash Diagrams	Description of Existing Crash Trends	→		Crash Reduction Estimation (CMF's)	→	Documentation
Existing Conditions	Calculation of Crash Rates	Crash Diagrams	Description of Existing Crash Trends	→				Documentation

E. Documentation

- 1) All crash data, analysis, and predictive crashes outlined above will be documented in a *Crash Data and Safety Analysis Technical Memorandum*.

Appendix C

Traffic Analysis Memorandum of Agreement

I-75 NORTH CORRIDOR MASTER PLAN

EXISTING CONDITIONS TRAFFIC TECHNICAL MEMORANDUM

Memo

Date: Tuesday, June 9, 2020

Project: I-75 from N. River Road to Moccasin Wallow Road PD&E
FPIDs: 442518-2 and 442518-3

To: Joshua Jester, FDOT

From: Smith Siromaskul, HDR

Subject: Traffic Analysis Memorandum of Agreement (MOA)

1. Purpose of the Memorandum of Agreement (MOA)

The Memorandum of Agreement (MOA) is being prepared based on discussions that occurred on November 22, 2019, between FDOT District One and the I-75 PD&E team. During this meeting, it was established that we are too early in the project process to have all of the information needed to develop a Methodology Letter of Understanding (MLOU).

The project area for this second of two I-75 corridor projects spans multiple counties and nearly 40 miles of I-75. The length of the corridor creates complications in the project process that this MOA is intended to address as there are elements on which concurrence should be obtained at this time instead of waiting until such time as an MLOU and subsequent SIMR can be developed.

The MOA outlines how analysis and documentation will be conducted for this study. The intent of the MOA is as follows:

- To document traffic operational analysis and traffic forecasting methodologies to be followed during the preliminary analysis phase of the I-75 PD&E Study. The preliminary analysis phase is defined as the phase where the I-75 PD&E team identifies the ultimate design for the corridor. This analysis will be summarized in a Traffic Technical Memo.
- To obtain concurrence from FDOT District One on traffic operational analysis and traffic forecasting methodologies, including traffic analysis tools to be used for the duration of the I-75 PD&E Study.

The preliminary analysis phase will help determine how the interchanges will be grouped, leading to Interchange Access Request (IAR) actions including SIMRs, IMRs, IOARs and IJR. Further alternatives for each IAR action will be determined based on the coordination with FDOT Central Office and FDOT District One during the MLOU stage consistent with the latest Interchange Access Request Users Guide (IARUG). Discussions about the appropriate level of IAR documentation for interchanges within the study area, will continue as the preliminary analysis phase progresses and more information becomes available. While deterministic tools will be used during the project for concept development purposes, the simulation models cover the entirety of the project area. In an effort to not duplicate efforts, we are proposing to report measures of effectiveness from simulation modeling. Additional discussion is in Section 10.

From an overall project perspective, we believe that the ultimate full corridor preferred alternative configuration must be determined as the initial aspects of the overall two-County Study. This needs to cover the entire corridor without regard to order of implementation or segmentation of the project into implementable pieces, because following construction under any phased implementation scenario, the whole of the corridor-wide improvements needs to work comprehensively together in the full build scenario. This ultimate solution needs to be based on the ultimate travel demand for the design year. This would represent the first traffic operational analysis scenario and we can refer to this as the ultimate design.

Subsequent to determining the ultimate design, we need to do two things:

- Identify the order in which the existing conditions will fail
- Find a way to segment the ultimate design into standalone projects that can be implemented while fitting into the ultimate framework with limited throwaway, and that have the ability to be operable on their own from a phased implementation scenario

This methodology will help determine how we should separate the interchanges into packages and the appropriate IAR documentation that would be associated with those groupings. This leads to our recommendation that a decision on how to segment the corridor should be made after determining the ultimate condition, and of course in part on the anticipated staggered programming of final design and construction funding. The ultimate condition would be determined via traffic operational analysis of the corridor as a whole.

2. Project Description

FDOT District One recently initiated a Project Development and Environment (PD&E) study for Interstate 75 (I-75) in Sarasota County and Manatee County. The study limits in Sarasota County start from east of CR 777 (N. River Road) to the Sarasota/Manatee County Line (22.8 miles). The study limits in Manatee County start from the Sarasota/Manatee County Line to north of Moccasin Wallow Road (16.5 miles). The PD&E study spans 39.3 miles in length and traverses the major urban areas of Sarasota and Bradenton in southwest Florida. I-75 also crosses the navigable Manatee River in Manatee County near the northern project limit. It should be noted that the PD&E study is not a re-evaluation.

The project segment of I-75 consists of a six-lane divided typical section with a maximum posted speed limit of 70 miles per hour. The functional classification of I-75 within the PD&E study limits is Urban Principal Arterial – Interstate. Existing right-of-way (ROW) along the corridor ranges from approximately 300 feet to 500 feet in width. While the proposed improvements are anticipated to be constructed primarily within the existing right-of-way, some additional right-of-way may be required, particularly around the interchanges. Specific right-of-way requirements will be determined during the PD&E Study.

This capacity improvement project involves the potential construction of managed lanes in each direction on I-75. Additional general use lanes, collector-distributor roadways, and auxiliary lanes, as well as interchange operational improvements, are also being considered. As such, up to a fourteen-lane typical section is being explored. There are also opportunities to operate reliable, efficient transit service within the managed lanes, as well as to provide connections to park and ride or kiss and ride lots located within the project area. Further, there

is opportunity to provide improved or new bicycle and pedestrian accommodations as well as landscaping/streetscaping treatments on roadways connecting to or passing under the interstate to enhance bicycle and pedestrian circulation and access to area transit service.

3. Purpose and Need Statement

The purpose of the PD&E project is to address the deficient operational capacity of I-75, also known as Florida's State Road (SR) 93, from east of CR 777 (N. River Road) in Sarasota County to Moccasin Wallow Road in Manatee County in order to accommodate future travel demand projected as a result of population and employment growth along the corridor. The project will evaluate the potential addition of managed lanes, including supporting additional general use lanes, collector-distributor roadways, and auxiliary lanes; interchange operational improvements will also be considered. Other goals of the project are to:

1. Preserve the operational integrity and regional functionality of I-75 (and, therefore, the regional transportation network) by complementing similar corridor improvements to the north and south, and
2. Enhance emergency evacuation and response times.

The need for this project is based on the following criteria:

Capacity: The project is anticipated to improve traffic operations along I-75 by increasing capacity and better dispersing traffic (i.e., separating managed lanes traffic from general use traffic). The traffic dispersal and reduced congestion can decrease vehicle conflicts and, therefore, enhance travel conditions of the corridor. I-75 within the project limits currently operates at Level of Service (LOS) B to E, with annual average daily traffic volumes ranging from 75,000 vehicles per day to 139,000 vehicles per day. Traffic volumes on the corridor are projected to increase to between 113,000 and 211,000 vehicles per day by 2045. Without improvements, the driving conditions will deteriorate below acceptable LOS targets.

Safety: I-75 serves as part of the emergency evacuation route network designated by the Florida Division of Emergency Management. Also designated as an evacuation facility of Sarasota and Manatee Counties, I-75 is vital in facilitating traffic during emergency evacuation periods as it connects to other major arterials and highways of the state evacuation route network [such as CR 777 (N. River Road) and US 301]. The project is anticipated to:

- Improve emergency evacuation capabilities by enhancing connectivity and accessibility to other major arterials designated on the state evacuation route network, and
- Increase the volume of traffic that can be evacuated during an emergency event.

System Linkage: As part of Florida's Strategic Intermodal System (SIS) highway network, I-75 plays a significant role in facilitating commuter, visitor, and freight traffic within the state. The proposed project improvements are part of a larger, regional set of projects on the interstate system to both the north and south (in Hillsborough, Pinellas, Polk, Charlotte, Lee, and Collier Counties) that are considering managed lanes and additional general purpose lanes, auxiliary lanes, etc. to increase the operational capacity of not only I-75, but I-4 and I-275 as well.

The intent is for all of these project improvements to work together to improve the overall reliability and performance of the interstate system in moving high volumes of goods and people at efficient speeds. It is important to note that managed lanes also create an opportunity for the provision of efficient and reliable transit service. As such, these improvements are critical to enhancing regional mobility. They are also key in preserving the operational integrity and regional functionality of the I-75 corridor as a whole.

4. Project Limits

This project is located along I-75 from east of CR 777 (N. River Road) in Sarasota County to Moccasin Wallow Road in Manatee County. The study area is shown in **Figures 1, 2, and 3**. The study limits in Sarasota County start from east of N. River Road to the Sarasota/Manatee County Line (22.8 miles). The study limits in Manatee County start from the Sarasota/Manatee County Line to North of Moccasin Wallow Road (16.5 miles). The PD&E study spans 39.3 miles in length and traverse the major urban areas of Sarasota and Bradenton in southwest Florida.

The study area includes twelve existing interchanges on I-75 and the system interchange at I-75 and I-275. The US 41 and I-275 interchange is included in the study area due to the close proximity to the I-75 and I-275 system interchange. An alternatives analysis is not anticipated at this location. The on-and off-ramps and merge/diverge areas for the existing interchanges are encompassed along I-75 and I-275. The arterial intersections are listed below:

I-75 at CR 777 (N. River Road)

- N. River Road & Venice Avenue
- N. River Road & Subdivision Entrance
- N. River Road & I-75 Southbound Ramp Terminal
- N. River Road & I-75 Northbound Ramp Terminal

I-75 at Jacaranda Boulevard

- Jacaranda Boulevard & Commerce Drive
- Jacaranda Boulevard & I-75 Northbound Ramp Terminal
- Jacaranda Boulevard & I-75 Southbound Ramp Terminal
- Jacaranda Boulevard & Executive Drive
- Jacaranda Boulevard & Oak Heritage Drive

I-75 at Laurel Road

- Laurel Road & Twin Laurel Boulevard
- Laurel Road & Pinebrook Road
- Laurel Road & I-75 Southbound Ramp Terminal
- Laurel Road & I-75 Northbound Ramp Terminal
- Laurel Road & Discovery Way
- Laurel Road & Haul Road

I-75 at SR 681

- SR 681 & Honore Avenue

I-75 at SR 72 (Clark Road)

- Clark Road & Gantt Road
- Clark Road & Catamaran Drive
- Clark Road & I-75 Southbound Ramp Terminal
- Clark Road & I-75 Northbound Ramp Terminal
- Clark Road & Queensbury Boulevard
- Clark Road & Hummingbird Avenue

I-75 at SR 758 (Bee Ridge Road)

- Bee Ridge Road & Maxfield Drive
- Cattlemen Road & Cattleridge Boulevard
- Bee Ridge Road & Cattlemen Road
- Bee Ridge Road & I-75 Southbound Ramp Terminal
- Bee Ridge Road & I-75 Northbound Ramp Terminal
- Bee Ridge Road & Mauna Loa Boulevard

I-75 at SR 780 (Fruitville Road)

- Fruitville Road & Cattlemen Road
- Fruitville Road & I-75 Southbound Ramp Terminal
- Fruitville Road & I-75 Northbound Ramp Terminal
- Fruitville Road & Coburn Road (west)
- Fruitville Road & Coburn Road (east)

I-75 at CR 610 (University Parkway)

- Cooper Creek Boulevard & Tourist Center Drive
- University Parkway & Cooper Creek Boulevard
- Cooper Creek Boulevard & University Town Center Drive
- University Parkway & I-75 SB Ramp Terminal
- University Parkway & I-75 NB Ramps Terminal
- University Parkway & Market Street
- University Parkway & Lawrence Building Driveway
- University Parkway & Town Center Parkway

I-75 at SR 70

- SR 70 & Creekwood Boulevard
- SR 70 & 73rd Lane
- SR 70 & I-75 Southbound Ramps
- SR 70 & I-75 Northbound Ramps
- SR 70 & Lena Road
- SR 70 & 87th Street
- Tara Boulevard & 55th Avenue
- Creekwood Boulevard & 52nd Place

I-75 at SR 64

- SR 64 & 62nd Street
- SR 64 & 65th Street
- SR 64 & 66th Street
- SR 64 & I-75 Southbound Ramp Terminal
- SR 64 & I-75 Northbound Ramp Terminal
- SR 64/Grand Harbour Parkway

I-75 at US 301

- US 301 & 51st Avenue
- US 301 & I-75 Southbound Ramp Terminal
- US 301 & I-75 Northbound Ramp Terminal
- US 301 & 60th Avenue
- US 301 & K-Mart Driveway
- US 301 & 18th Street

I-75 at Moccasin Wallow Road

- Moccasin Wallow Road & Gateway Boulevard
- Moccasin Wallow Road & Gillette Road
- Moccasin Wallow Road & I-75 Southbound Ramp Terminal
- Moccasin Wallow Road & I-75 Northbound Ramp Terminal
- Moccasin Wallow Road & Buffalo Road
- Moccasin Wallow Road & 71st Avenue East

I-275 at US 41

- US 41 & 73rd Street
- US 41 & I-275 Westbound Ramp Terminal
- US 41 & I-275 Eastbound Ramp Terminal
- US 41 & 85th Street

Figure 1. Project Location and Study Area

Figure 2. Project Location and Study Area

Figure 3. Project Location and Study Area

5. Project Schedule

Submittal of Final Design Concept Plans is tentatively scheduled for November 2022. The public hearing is tentatively scheduled for February 2023.

Funding for the PD&E study is in the currently adopted Five-Year Work Program as listed below:

- 442518-2: I-75 (SR 93) from University Parkway to Moccasin Wallow Road, PD&E/EMO Study, FY 2019/2020
- 442518-3: I-75 (SR 93) from CR 777 (N. River Road) to University Parkway, PD&E/EMO Study, FY 2019/2020
- Strategic Intermodal System (SIS) Long Range Cost Feasible Plan FY 2029-2045 has identified funds for subsequent phases including PE and ROW

6. Analysis Scenarios

Analysis will be conducted for the following scenarios to identify appropriate IAR actions for interchanges within the project limits:

- Existing (2019)
- No-Build (2025 and 2045)
- Ultimate Build (2025 and 2045)

The analysis scenarios are described as follows:

- The Existing scenario represents the existing condition as it was during the count program and will be used for developing and calibrating a baseline scenario.
- The No-Build scenario is the existing configuration plus any planned improvements unrelated to this PD&E. This includes planned improvements with construction phases identified in cost feasible plans and due to be in place by the most recently adopted county LRTP horizon years for the travel demand model being used. The No-Build scenario will include all horizon year improvements regardless of the analysis year.
- The Ultimate Build scenario will, by definition, meet the needs of design year traffic in the ultimate configuration when all of the implementation phases have been completed.

A Traffic Technical Memo (Non-IAR) will be developed to document the segmentation process and supporting analysis for the phased implementation of improvements.

7. Alternatives

The following alternatives will be considered during the preliminary analysis phase of the project using the Design Year traffic forecasts for I-75 and interchanges within the project limits.

- No-Build Alternative: The No-Build (no action) Alternative will include currently planned and programmed improvements or projects currently under design.
- Ultimate Design Alternative: The Ultimate Design Alternative will include all recommended mainline and interchange improvements within the PD&E study area. Transportation System Management and Operations (TSM&O) improvements, including ramp metering and signal upgrades, will also be evaluated as part of the Ultimate Design Alternative in coordination with FDOT District One.

Subsequent to determining the ultimate design, the following tasks will be performed:

- Identify the order in which the existing conditions will fail.
- Segment the ultimate design into standalone projects that can be implemented while fitting into the ultimate framework with limited throwaway, and that have the ability to be operable on their own from a phased implementation scenario.

The Ultimate Design Alternative will evaluate managed lanes and determine the location of ingress/egress points and direct connect ramps for the entire I-75 corridor. The ingress/egress points for the ultimate design will impact how the corridor is segmented. The segmentation plan will also include an evaluation of the full I-75 corridor, which is required for the managed lanes module to be effective, but the managed lanes and ingress/egress points may only cover a certain segment of I-75.

8. Data Collection

Transportation System Data

Available existing traffic data for the I-75 mainline and ramps will be obtained from FDOT District One. All other traffic data will be determined using the procedures described below. Sources of information to be collected shall include, but not be limited to:

- Straight Line Diagrams (SLDs);
- Roadway Characteristic Inventory (RCI) Data;
- Florida Geographic Data Library (FGDL) Geographic Information System (GIS) Data;
- FDOT Standard Indexes;
- FDOT Traffic Information.

Existing and Historical Traffic Data

Data collection for the study shall consist of information from various sources. It shall be comprised of existing information and field collected data. Sources of information to be collected shall include, but not be limited to:

- Latest Five-Year Crash History;
- StreetLight Insight Origin-Destination (OD) Data – to be obtained from the FDOT District One Interstate Program Manager (IPM) and used to validate the OD matrices developed for the Vissim simulation;
- Traffic Count Information; and
- District One Regional Planning Model (D1RPM) 2015 and 2040 Cost Feasible Model

Traffic Counts:

In accordance with the Manual on Uniform Traffic Studies (MUTS) and the Project Traffic Forecasting Handbook, field traffic count data will be collected at the 13 existing interchanges as shown in **Attachment A**. The traffic counts will include 3-day classification counts, 3-day bi-directional volume counts, and typical weekday AM and PM peak period (7-9 AM and 4-6 PM) turning movement counts. The intersection traffic counts will include pedestrian, bicyclist, and truck volumes. A peak hour volume summary will be provided by approach.

In addition to the ramp terminal and adjacent intersections, several local intersections are being included in the analysis as their traffic flow may change due to the proposed improvements. These intersections are on the local network stemming off the study arterials and are not expected to have an impact on the freeway or interchange operations. They will be included in the simulation models to generate platooning and to verify that they do not cause queue spill back into the study arterial intersections. Additional traffic counts may be needed at other locations depending on the alternative configuration being analyzed.

Crash Data:

Crash data will be collected from the FDOT Crash Analysis Reporting System (CARS) along mainline I-75 and state facilities and supplemented with the University of Florida's Signal Four Analytics. The data collected will include the number, type and location of crashes, number of fatalities and injuries, and estimates of property damage and economic loss. Crash data will be obtained for the I-75 mainline from east of N. River Road to north of Moccasin Wallow Road and for each of the primary cross streets identified in **Attachment A**.

Field Data:

Additional field data will be collected for microsimulation calibration purposes including I-75 mainline peak period speeds from the Regional Integrated Transportation Information System (RITIS) and arterial travel times using Bluetooth stations. Field visits will also be conducted to collect information on existing driver behavior and congestion levels, and to verify signal phasing information such as protected/permitted left-turn operations, right-turn-on-red restrictions, phasing, etc. Existing signal plans and timing information for signalized intersections will be gathered from Sarasota County and Manatee County.

Land Use Data

Existing and future land use data within the area of influence will be obtained from the adopted Sarasota County and Manatee County Comprehensive Plans.

Environmental Data

Environmental data and impacts will be investigated in the ongoing PD&E study. All available environmental data from ETDM and other studies will be considered during the environmental analysis of alternatives. The FDOT's Area of Interest (AOI) Tool in the Efficient Transportation Decision Making (ETDM) process will be utilized to establish a project buffer that identifies pertinent environmental features within a 300-foot swath of land measured from the existing right-of-way. The preliminary environmental impacts of implementing the proposed Build Alternative improvements shall be documented in any IAR resulting from the Traffic Technical Memorandum developed for this study. The following environmental reports will be prepared, as documented in the ETDM Screening Report, as part of the PD&E Study:

- Environmental Document (Type II Categorical Exclusion);
- Noise Study Report;
- Sociocultural Effects Evaluation (SCE);
- Air Quality Technical Memorandum;

- Level I Contamination Assessment Report (Contamination Screening Evaluation Report);
- Conceptual Stage Relocation Plan;
- Water Quality Impact Evaluation;
- Natural Resource Evaluation (Wetlands, Species and EFH);
- Conservation Measures and Mitigation Plan;
- Cultural Resource Assessment Survey Addendum;
- Section 4(f) Determination of Applicability (DOA);
- Wild and Scenic Rivers, Navigable Waterways, and Coastal Zone Management Assessment

Planned and Programmed Projects

This project will consider all programmed and planned roadway improvements in the area. Planned and programmed projects will be consistent with adopted Cost Feasible Plan and FDOT Work program. The project team will coordinate with project stakeholders including FDOT, Sarasota County, Manatee County, and the Sarasota-Manatee Metropolitan Planning Organization (MPO) within the project study area and will obtain concurrence with FDOT District One prior to incorporating them in the study. These capacity improvements will be consistent with those specified in the regional transportation plans including the following:

- FDOT 5-Year Adopted Work Program;
- FDOT SIS plans;
- FDOT State Transportation Improvement Program (STIP);
- Committed improvements from local and private sources;
- Sarasota-Manatee MPO Long Range Transportation Plan (LRTP);
- I-75 at Clark Road studies and design plans;
- I-75 from South of Bee Ridge Road to South of Fruitville Road studies and design plans;
- I-75 at Fruitville Road studies and design plans;
- SR 780 (Fruitville Road) Corridor Vision Plan;
- I-75 at SR 70 studies and design plans;
- I-75 at SR 64 studies and design plans;
- I-75 at US 301 studies and design plans;
- Developments of Regional Impact (DRIs) within the area;
- PD&E studies and master plans within the area; and
- Unified Planning Work Program (UPWP) (if applicable).

These projects will be documented in the Traffic Technical Memo and IAR documents.

9. Travel Demand Forecasting

A specially validated version of the District One Regional Planning Model (D1RPM) with an enhanced 2015 base year and 2040 horizon year will be used to develop traffic forecasts for the Sarasota and Manatee County I-75 PD&E Study. This model version was created in support of the FDOT managed lanes efforts focused along I-75 and was prepared by and provided by the IPM team. Linear extrapolation will be leveraged to forecast the developed 2040 horizon year model to the 2045 design year for the project.

All volume development and traffic forecasts for the project will be documented in a Project Traffic Development Memorandum. With the proposed segmentation plan, volumes will be developed for the AM and PM peak periods for the following scenarios:

- Existing (2019)
- No-Build (2025 and 2045)
- Ultimate Build (2025 and 2045)

10. Traffic Operational Tools and Analysis

Interchange design configurations will range from standard to complex geometry involving managed lanes and CD systems. Therefore, traffic operational analysis will be performed for both the AM and PM peak periods using PTV's Vissim microsimulation software. The operational analysis will utilize the most recent version of Vissim¹ to calibrate existing conditions. Once calibration has been completed, any major Vissim software updates will be tested to determine if the models can be updated to the latest version without requiring significant re-calibration efforts. Given the duration of the project, using the most up-to-date version of the software that does not affect the analysis results is preferred and any changes will be documented in subsequent IARs.

Calibration Methodology

Vissim models using 15-minute flow rates will be developed for a 3-hour AM and PM peak period and calibrated to existing conditions. The two shoulder hours outside the peak hour will account for traffic buildup and dissipation characteristics within the AOI. The 2019 update of FHWA's Traffic Analysis Toolbox Volume III: Guidelines for Applying Traffic Microsimulation Modeling Software and 2014 FDOT Traffic Analysis Handbook will be used as a guideline for the development of the project Vissim models.

Existing Conditions Vissim Model Development:

- Subarea Vissim models will be developed for each interchange area. A 30-minute seeding period will be used for the arterial inputs. Once the model is developed and error-checking has been performed, the subarea models will be calibrated to accurately replicate the traffic performance for the existing conditions for the interchange. The arterial models will be calibrated to Bluetooth travel time data and supplemented with site observations.
- A Vissim model for the I-75 mainline and ramps will be developed for existing conditions. The I-75 mainline model will utilize a 60-minute seeding period and will be calibrated using speed data from RITIS. Observed queue spillback onto the mainline from the ramp terminals will require the addition of the ramp terminal signal in order to calibrate the mainline subarea, otherwise the ramp terminal intersections will not be included in the I-75 mainline model.
- Subarea Vissim models will be merged into one single model by combining the interchange models with the I-75 mainline model. A 60-minute seeding period will be applied for the entire model. Once the model is developed and error-checking has

¹ As of June 9, 2020, the most recent version is Vissim 2020.

been performed, adjustments may be required at the locations where the models are tied together to ensure that the models accurately replicate the traffic performance for the existing conditions.

- Existing Vissim models will be validated to the 2019 existing year traffic counts and OD patterns.
- The calibration of the existing AM and PM peak period models will target the thresholds indicated in the FDOT Traffic Analysis Handbook Table 7-7 Classical Model Calibration Targets shown in **Table 1**.

Table 1: Vissim Calibration Targets¹

Calibration Criteria	Calibration Target/Goal
Traffic Volume	Simulated and measured link volumes for more than 85% of links to be: <ul style="list-style-type: none"> • Within 100 vph for volumes less than 700 vph • Within 15% for volumes between 700 vph and 2700 vph • Within 400 vph, for volumes greater than 2700 vph.
	Simulated and measured link volumes for more than 85% of links to have a GEH statistic value of five (5) or lower.
	Sum of link volumes within calibration area to be within 5%.
	Sum of link volumes to have a GEH statistic value of 5 or lower.
Speed	Modeled average speeds on I-75 to be within +/- 10 mph of field-measured speeds on at least 85% of all RITIS detector locations.
Travel Time	Modeled arterial travel times within 15% (or 1 min, if higher) for more than 85% of segments.
Visualization	Check consistency with field conditions of the following: on- and off-ramp queuing; weaving maneuvers; patterns and extent of queue at intersections and congested links; lane utilization/choice; location of bottlenecks; etc.
	Verify no unrealistic U-turns or vehicles exiting and reentering the network.

¹source: FDOT Traffic Analysis Handbook, Table 7-7 Classical Model Calibration Targets.

Future Conditions Vissim Model Development:

- The design year simulation models will utilize the adjusted parameters used to calibrate the existing conditions models.

Selection of Measures of Effectiveness (MOE)

Site-specific MOEs used to evaluate and compare the alternatives will be as follows:

- Signalized/unsignalized Intersections – Volume, control delay, maximum queue lengths;
- Arterial Segments – Volume, travel speed, travel time, maximum queue lengths.
- Freeway Segments – Volume, density, travel speed, congestion charts; and
- Off Ramps – Volume, maximum queue lengths.

Split intersections or other concepts that require multiple signals or adverse travel will include travel time by movement to and from consistent locations. Consistent with the 2014 FDOT Traffic Analysis Handbook Section 8.4.3, level-of-service (LOS) computed from microsimulation analysis will be reported as an “estimated LOS”. Freeway segments and ramp merges, diverges, and weaves will be evaluated using Vissim and compared to HCM thresholds for

determining estimated LOS. Intersection and arterial operations will also be evaluated using Vissim and compared to HCM metrics.

In addition to the site-specific MOEs mentioned above, network-wide MOEs will also be evaluated and are described below:

- Total Travel Time;
- Total Delay Time;
- Vehicles Arrived;
- Average Delay Time;
- Latent Delay Time;
- Latent Vehicles; and
- Total Delay plus Latent Delay.

Capacity Analysis Tools

Capacity analysis tools, including HCS and Synchro, may be used for a high-level screening of alternatives during the concept development process. HCS and Synchro tools and results will not be included in the Traffic Technical Memo.

11. Safety Analysis

Historical crash data within the study area will be obtained from the FDOT Crash Analysis Reporting System (CARS) database for the most recent five-year period available (2013-2017). The CARS data will be obtained from the FDOT Safety Office for the mainline, interchanges, and major cross streets within the area of influence and will be supplemented with information gathered from the Signal Four Analytics tool. The data collected will include crash number, type, location, and severity. Utilizing the information obtained from the crash data, an evaluation of existing conditions will be performed early in the study process to aid in the development of the ultimate design. A summary of existing crash history will be included in the Traffic Technical Memo.

An objective and quantitative evaluation of the proposed improvements on traffic safety along the corridor will be performed by utilizing FHWA's Crash Modification Factor (CMF) Clearinghouse and applying the Highway Safety Manual (HSM) predictive method process, where appropriate. Any crash prediction will be conducted utilizing the methodologies and guidance provided by the HSM and associated supplemental documentation. A detailed accounting of this methodology will be provided for Department review and approval prior to application.

12. Consistency with Other Plans/Projects

The I-75 PD&E will maintain consistency with the Sarasota/Manatee MPO LRTP, I-75 interchange improvements at Clark Road, Fruitville Road, SR 70, SR 64, and US 301, and the I-75 widening project from south of Bee Ridge Road to south of Fruitville Road. Any planned improvements unrelated to this PD&E with construction phases identified in cost feasible plans and due to be in place by the most recently adopted county LRTP horizon years for the travel demand model being used will be incorporated into the future No-Build and Build scenarios

developed as part of this study. The IPM will include these improvements in the travel demand model that is being provided. If proposed improvements are inconsistent with any plan, steps to bring the plan into consistency will be developed.

13. Environmental Considerations

A Type II Categorical Exclusion (CE2) is being prepared and key environmental findings from the CE2 will be added to each IAR. Permit requirements will be coordinated with the following agencies as part of the ETDM and NEPA process: U.S. Army Corps of Engineers, U.S. Fish and Wildlife Service, Southwest Florida Water Management District, Florida Department of Environmental Protection, and Florida Fish and Wildlife Conservation Commission.

Limited right-of-way is acquisition is anticipated to construct the proposed Ultimate Build Alternative improvements. No significant environmental impacts are anticipated. Information concerning the status of the Environmental Approval and the permitting process will be included in IARs.

14. Coordination

An appropriate effort of coordination will be made with proposed developments in the area. A review of future network changes and land use growth will be performed as part of the travel demand model's subarea validation, which is an effort being undertaken by the IPM for this PD&E project. The IPM will summarize and distribute network and land use change information to stakeholders including FDOT, Sarasota County, and Manatee County for concurrence. Based on stakeholders' inputs, and after approval from FDOT District One, the changes will be incorporated into the travel demand model. Coordination with the IPM will be made before proceeding with project-level traffic forecasts. Project level traffic forecasts (AM and PM peak hours) will be developed by the PD&E project team using the travel demand model that is provided by the IPM as the base. All future year Vissim models will include all cost feasible improvements that exist within the project limits. The IPM will provide a list of the network and land use changes to the project team as part of the travel demand modeling documentation for inclusion in the Traffic Technical Memo and IAR documents. This coordination will occur before the development of traffic forecasts.

15. Anticipated Design Exceptions and Variations

If an exception/variation should arise for the Ultimate Build scenario, it will be processed per FHWA and FDOT standards.

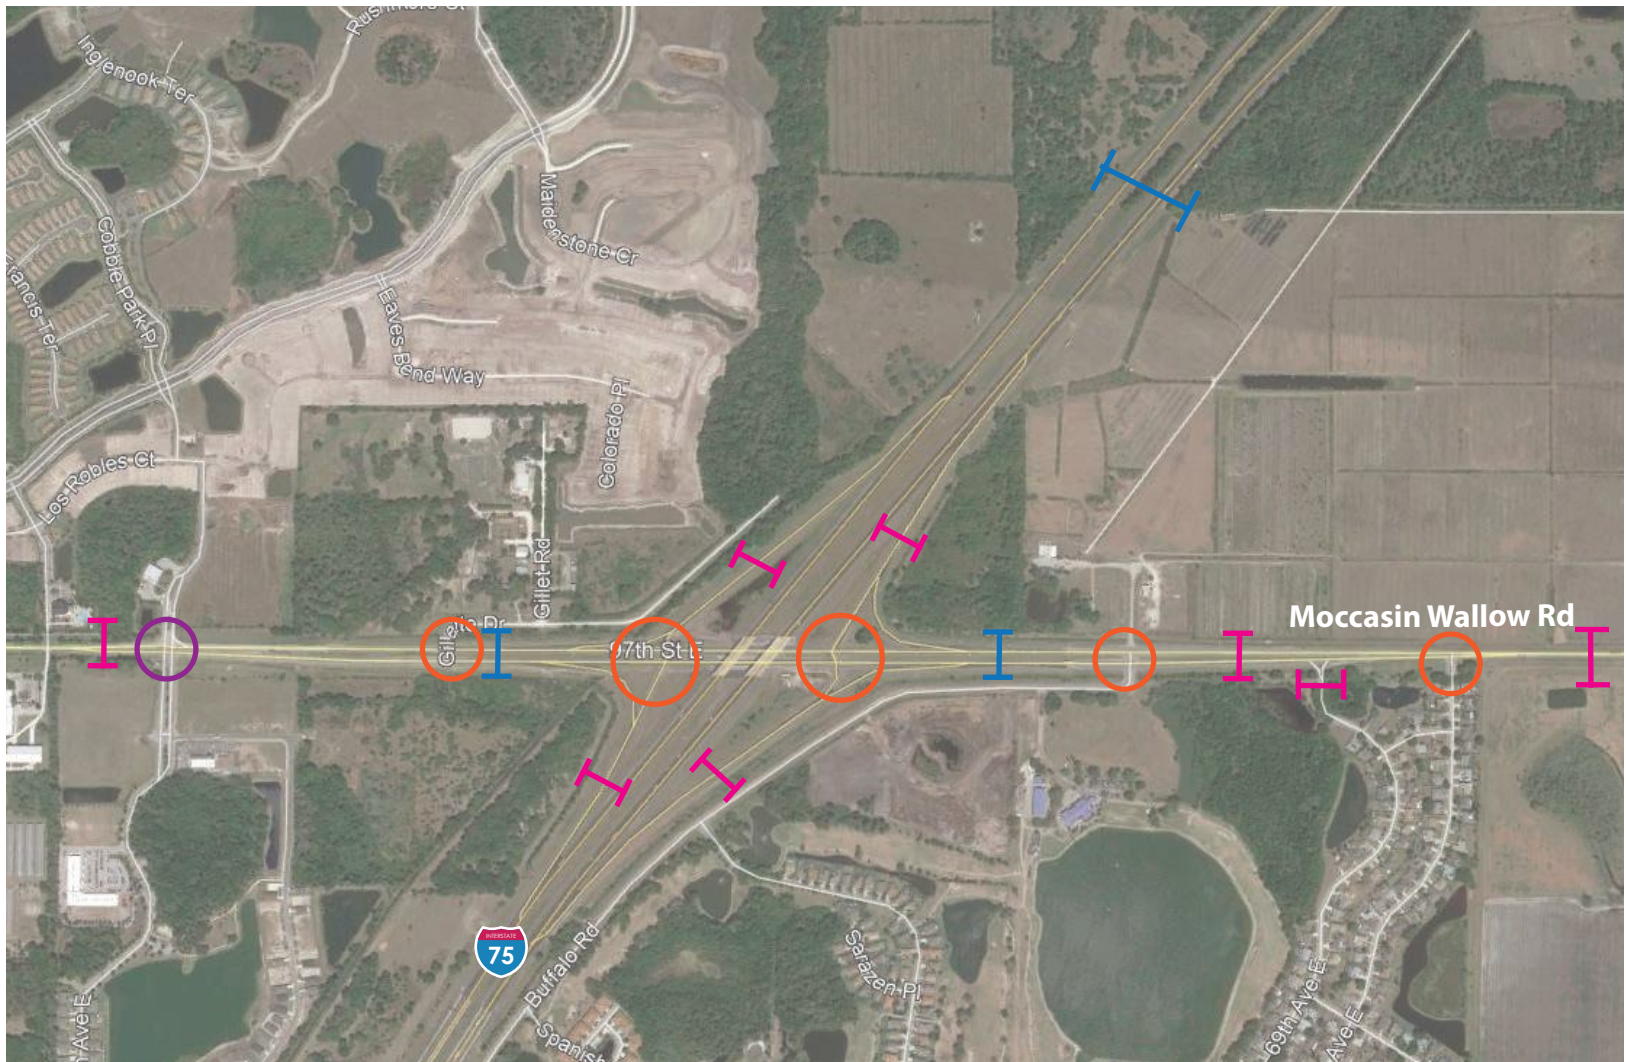

16. Conceptual Signing Plan

A conceptual signing plan will be developed for the Ultimate Build scenario. The conceptual signing plan will provide major guide sign placement and messages. The conceptual signing plan will be prepared in accordance with all applicable FDOT, FHWA, and MUTCD guidelines.

17. Access Management Plan

The improvement may affect access management within the study area. An access management plan will be developed for the Ultimate Build scenario to complement the improvements to the interchanges.
